The distinct concept of 'human' rights arose in the aftermath of World War II, with the widespread condemnation of the atrocities the Nazis committed against Jews and other minorities. After having declined in the wake of skepticism and new political movements in the nineteenth and twentieth centuries (e.g., utilitarianism, emotivism, nationalism, and Marxism), notions associated with natural rights and natural law enjoyed a revival in the aftermath of the war, as democratic theorists regained respect for more objective moral principles that provide standards by which to evaluate the practices of states. Such theorists as Leo Strauss (1950) and Edward Purcell (1973) have written about a postwar 'crisis' in democratic theory along these lines. The term 'human' rights avoided the intellectual and political baggage associated with 'natural' law and rights, while at the same time pointing to universally held moral principles. In the unprecedented Nuremberg trials held after the war, Allied prosecutors convicted Nazi leaders of crimes against peace and humanity. Also, in the wake of World War II, the new United Nations (UN) made human rights an important part of its agenda, and Japan and West Germany, under the aegis of occupying forces, adopted constitutions that protect basic civil liberties and rights.

Relationship to the State

The concept of individual or natural rights is historically and pragmatically related – both positively and negatively – to the emergence of the modern nation-states from feudalism between the thirteenth and seventeenth centuries. In 1648, the Peace of Westphalia, which ended the murderous Thirty Years' War in Europe between Catholic and Protestant states, constituted the first formal international recognition of the nation-state's autonomy from religious authority. It also established the first official tolerance of religious pluralism, a crucial move in the rise of civil liberty and human rights. Yet the Westphalian model of international law left no room for the international enforcement of individual rights, as its main objective was the recognition of the principle of territorial sovereignty (domestic jurisdiction) of strong states.

Nonetheless, the rise of strong nation-states made individual rights more important than they had been in the past, spawning new theories about the obligations of states to citizens. Indeed, another paradox (which also involves the endemic jurisprudential debate between legal positivism and forms of legal analysis based on natural law) concerns the relationship between rights claims and their enforcement or recognition (*see* Natural Law). Though many theorists persuasively contend that rights claims exist independently of legal protection, rights claims (positive and negative) have to be recognized and enforced by those in power in order to be effective. The Nuremberg trials present a classic example of this fact. (Some have called the verdicts 'victors justice'.) As James Madison wrote, following the logic of Hobbes and Locke, liberal freedom can exist only when the state is strong enough to protect its citizens, but also limited enough so as not to oppress them. Writing in the aftermath of World War II, Hannah Arendt (1951) chillingly portrayed how vulnerable stateless people are to abuse of their humanity. Legal theorist Stephen Holmes (1995) puts the matter succinctly: "Weak-state pluralism is a recipe not for liberalism, but for a proliferation of rival and coercive mafias, clans, gangs, and cults … Liberal government … is meant to solve the problem of anarchy *and* the problem of tyranny within a single and coherent system of rules" (pp. 270–271).

Some Basic Issues

Important questions have been raised about the content and intellectual foundation of human rights and civil liberties. What is the scope of rights? Are such rights derived from political or legal agreement, or are they postulates of theological or philosophical inquiry? Do we grasp them by intuition or reason? Which claims are fundamental, and which less fundamental, and how can we make this determination? Should the list of fundamental claims include only basic political and civil liberties, or should it also include social and economic rights? Are rights claims culturally determined or relative, as the American Anthropological Association officially declared in 1947, or are there general principles that make certain claims universal?

Some thinkers, such as Christian Bay (1982), maintain that human rights stem from human 'needs,' which include shelter, food, and livelihood; others emphasize human beings' distinctive moral nature, stressing human dignity, self-respect, and citizenship. The debate concerns those who define human nature in largely materialistic or naturalistic terms, and those who define human nature in terms of such qualities as rationality, moral capacity, or spirituality.

Writers such as Henry Shue (1980) distinguish basic from less basic rights. A right is basic if its enjoyment is 'essential to the enjoyment of all rights.' These rights include physical security, economic security or subsistence, and liberty to

participate in the economic and political life of the community. Still others, such as Donnelley, argue that this list is insufficient because a fully developed life requires more opportunities and attributes than these minimums. However, history shows that 'negative' civil liberties are necessary to protect us from the state, so these should always be on the short list of basic rights. If we decide to include more rights as basic, we must do so without sacrificing basic civil liberties. (This is the approach of philosopher John Rawls in his classic book *A Theory of Justice* (1971): no scheme of social justice may negate fundamental civil liberties.) And we must understand that the longer the list of basic rights, the greater the potential for conflict among rights and social policies designed to promote them.

Theorists such as French jurist Karel Vasak (1982) posit 'generations' of rights based on historical development. The first generation consists of political and civil liberties, while the second generation embraces egalitarian social and economic rights. The so-called third generation rights involve humanity as a whole, including cultural self-determination, environmental health, solidarity, and peace.

The founding movements and documents in the rise of liberal democracy accentuated civil and political liberties. Yet the rise of socialism, Marxism, and the working class in the nineteenth century spawned the advocacy of social and economic rights in addition to (or instead of) civil and political rights. In the twenty-first century, such rights are found in the constitutions or fundamental laws of communist (and former communist) states and many developing or third world states (*see* Socialist Law; Postcolonial Law). Though developed liberal states are mainly dedicated to political and civil rights, social and economic rights often comprise parts of their social and legislative policy. In recent decades, such internationalist groups as the Lawyers Committee for Human Rights and the Fair Labor Association contend that corporations' use of factories in developing countries has made the protection of economic and social rights in those countries a primary concern.

Human rights covenants in the UN reflect these debates (*see* International Law and Treaties). In 1946, the Economic and Social Council of the UN established the Commission on Human Rights, which led to the Universal Declaration of Human Rights in 1948, a foundational document that has achieved the status of customary international law. In 1966, the International Covenant on Civil and Political Rights (ICCPR) and the International Covenant on Economic, Social, and Cultural Rights (ICESCR) were signed by most states, taking effect in 1976 (*see* Torture: Legal Perspectives). The ICCPR protects such basic civil liberties as freedom from arbitrary punishment, forced servitude, and unfair criminal process; freedom of thought, conscience, and religion; personal liberty and security; freedom of the family; freedom to participate in fair elections; and equal suffrage. An Optional Protocol of the ICCPR commits ratifying states to allow a special committee of experts to examine claims by individuals against them.

The ICESCR covers such rights as the right to work under good conditions; the right to an adequate standard of living; and the right to social security, food, clothing, shelter, and basic health. The ICESCR is less stringent in its wording than the ICCPR. Signatories established no rank ordering of these rights, and enforcement is more a matter of exposure and persuasion than force.

Civil Liberties in Practice

The protection of civil liberties varies (in legal provisions and applications of these provisions) in different countries due to cultural and political factors (*see* Constitutionalism, Comparative). For instance, free speech doctrine and practice in the United States protect the advocacy of illegal action, including racist rhetoric that falls short of directly triggering a disturbance of the peace or inciting violence. In contrast, Canada, Israel, Germany, France, and many other countries prohibit speech that advocates racism (racist rhetoric), regardless of the likelihood of illegal action. In Germany and Austria it is illegal to belong to a Nazi party or to wear a Nazi uniform, while courts in the United States have expressly protected such actions.

Though virtually all countries have basic legal protections for criminal suspects, standards vary widely, especially when we look at practice rather than the letter of the law. In Russia, for example, where legal institutions are poorly developed, preventive detention and criminal procedure rights of criminal suspects are poorly enforced despite formal legal protections; France offers some protections but does not recognize the privilege against self-incrimination. In the area of religion, the United States maintains an exceptionally strict separation of church and state, while such democracies as Ireland, Italy, and Germany allow more accommodation between state and religion. In India, 'personal laws' linked to the major religions (Hindu, Muslim, Christian, and Parsi) are distinguished from normal civil law, thereby accommodating culturally based discrimination against women in such areas as marriage, divorce, and inheritance. Communist China has persecuted such religious groups as Christians and the Falun Gong because their views are allegedly contrary to state ideology. And such Muslim countries as Saudi Arabia, Iran, and Pakistan have severe laws against blasphemy (disparaging religion), a form of speech that the American First Amendment protects without qualification.

Social scientists and legal scholars cite several factors that influence the extent to which countries will support civil liberties and rights on a sustainable basis. Commitment to civil liberty has historically been accompanied by social pluralism, legal institutions based on rule of law, and the differentiation of the state from civil society (*see* Rule of Law (and Rechtsstaat); Law and Development). More specific explanations include such factors as the existence of a bill of rights and judicial independence, judicial leadership and control of case dockets, and a culture of rights consciousness that encourages citizens to think in terms of rights (*see* Judicial Review; Legal Culture and Legal Consciousness; Rights: Legal Aspects).

More recent explanations point to the presence of political and social movements that engender legal change (e.g., the civil rights movement in the United States; the freedom movement of South Africa led by Nelson Mandela). Charles Epp (1998) has pinpointed sustained pressure exerted by a 'support structure for legal mobilization,' which consists of rights-advocacy organizations and lawyers, and sufficient

funding from private and (especially) public sources. Rights revolutions succeeded in the United States and Canada in recent decades because of the presence of these factors, while India's rights movement was thwarted despite a favorable Supreme Court because such factors were absent (*see* Law as an Instrument of Social Change).

Whether the 'Arab Spring' that erupted in Egypt and Tunisia in 2010 and spread to other Middle Eastern countries will result in greater freedoms and civil liberties in that region is an open question as of this writing. It will depend upon the strength of the factors considered herein.

Human Rights in International Practice

Until recently, the international system remained committed to the Westphalian model's strong presumption in favor of the 'domestic jurisdiction' of states. But this situation slowly began to change with the growth of consciousness of human rights, the democratic ethic, and globalization (*see* Globalization: Legal Aspects). The most important events before the end of World War II and the Nuremberg trials include the abolition of slavery in the British empire in the 1830s and 1840s, culminating in the League of Nations' Slavery Convention of 1926; the policy of 'humanitarian invention' by Western states to protect Christian citizens abroad in the nineteenth century; and several conventions and treaties protecting the rights of soldiers in war promulgated in the nineteenth and twentieth centuries.

In the wake of World War II and the humiliating failures of the League of Nations, the world community established the United Nations, which promulgated the UN Charter. Whereas the Westphalian model is premised on the freedom of states over their domestic jurisdictions, the UN Charter, or 'new international law' model, embraces the Kantian model of international relations and law, which emphasizes universal peace and human dignity. In reality, the models coexist in the contemporary world, posing sometimes vexing questions about where to draw the line between state sovereignty and international human rights norms. Such questions are not merely abstract problems, as supranational bodies face them on a regular basis. Yet the conferees who established the charter rejected a proposal to authorize intervention to protect rights, and a clause in the charter expressly prohibits intervention in 'matters which are essentially within the domestic jurisdiction of states.'

In recent decades, many international treaties and forums have been established under the aegis of the UN or other regional and international organizations to promote recognition of human rights (*see* International Law and Treaties). States have signed treaties in conventions against torture, genocide, racial and gender discrimination, and treaties protecting refugees and children. Again, legal, social, and political movements have been indispensable to the promotion of human rights logic and practice, as the noted human rights activist Ayreh Neier chronicled in an authoritative book (2012). In addition to hundreds of regional and intergovernmental organizations (such as the Organization of American States, the Organization of African Unity, etc.), such nongovernmental organizations as Amnesty International, Human Rights Watch, and the International Committee of the Red Cross have played major roles in raising awareness, linking international organizations, and even bringing cases for enforcement in relevant jurisdictions (Keck and Sikkink, 1998).

States have drafted regional agreements to protect rights on all continents except Asia. In Europe, the European Convention of Human Rights and Fundamental Freedoms (based on the ICCPR) formed the European Court of Human Rights, which takes cases after they have been heard by the relevant domestic courts (*see* European Union Law). Member states have agreed to accept all of the court's rulings, leading, for example, to changes in Britain's law of criminal procedure (most notably in the area of pretrial detention) and changes in several states' laws concerning the rights of children born out of wedlock.

Not surprisingly, politics has affected the application of the ICCPR and ICESCR covenants. During the cold war era, Western countries championed the ICCPR, while communist countries supported the ICESCR. Third world countries have advocated rights of self-determination, cultural rights, and collective rights concerning resources (debates over law of the seas, etc.). Cultural relativism remains an issue. In 1993, Asian countries challenged claims about the universality of political and civil rights during the UN World Conference on Human Rights, arguing that such rights can be counterproductive, even dangerous, in the context of economic underdevelopment, fragmented nationalism, and fragile state institutions. Theorists such as Donnelley counter by pointing out that these arguments ignore the actual plights of persecuted minorities in these countries, thereby serving the interests of entrenched elites or tyrants. Similar concerns are raised about the status of women in many states, such as Saudi Arabia and Iran.

Enforcement of human rights at the international level has remained problematic because of the continued normative and prudential reluctance to intervene in the domestic jurisdiction of states. Hobbes and Locke would have predicted such a result in the absence of an international sovereign with sufficient power to enforce protections of rights. As a result, the main support for human rights has been in the form of moral persuasion (far from meaningless, if not always efficacious), exposure of violations through research and publication, and the deployment of such measures as economic sanctions. UN organizations have investigated several countries, including Chile, Rwanda, Somalia, Zaire, several Latin American countries, Iran, Iraq, and South Africa. Such investigations are no substitute for political will, however.

Victories and Defeats: The Continuing Dilemma of Rights and the State

The decline of cold war politics in the UN Security Council enabled the UN to be somewhat more aggressive, sponsoring peacekeeping and actual interventions to protect human rights in Somalia, Iraq, and Bosnia in the early 1990s. Yet the efforts in Somalia and Iraq after 1991 proved short lived, and in 1994 the world stood by while massive genocide took place in Rwanda (Straus, 2006). In 1999, Cuba, China, and Sudan championed the norm of the territorial sovereignty of states in order to shield their abuses of human rights from international intervention, even though these states were at

that time themselves members of the UN Human Rights Commission.

To be sure, Yugoslav president Slobodan Milosevic was defeated in his attempt to take over Kosovo in 1999, yet this victory was won by the military commitment and might of the North Atlantic Treaty Organization under the leadership of the United States and Britain; victory came only after Serbian forces had already carried out massive ethnic cleansing. After Kosovo, Czech president Vaclav Havel wrote in *Kosovo and the End of the Nation-State* that the nation-state would end in the next century, giving away to an international community governed 'by universal or global respect for human rights, by universal civic equality and the rule of law, and by a global civil society.' Writer Leon Wieseltier (1999) replied that no oppressed soul had ever been saved by the forces of 'global civil society.' Kosovo was delivered from Milosevic by the willful acts of allied nation-states. Though the nation-state is a source of evil, 'it is also the nation-state from which we may demand rescue from such evils. The ethical content of a particular sovereignty is what finally matters.'

In 2011, a military intervention sponsored by the UN assisted the revolutionary movement of Libya in its fight against its tyrannical ruler, Muammar Gaddafi. This effort – led by the military power of the West, which regretted its failure to intervene in Rwanda 17 years earlier – succeeded in deposing Gaddafi; but the weakness of the new state in Libya has resulted in a chaotic situation as of this writing. The paradox of state power and rights perseveres.

The Special Problems Posed by International Terrorism

The emergence of violent Islamic extremism, epitomized by the terrorist attacks on the United States on September 11 2001, has created special quandaries for human rights and civil liberties, and for the applicability of governing standards of international law and the laws of war (*see* Law and Terrorism in the US and Beyond; International Law and Treaties) (Cassese, 2001). Terrorist threats before 9/11 were typically addressed through traditional criminal law enforcement, which is based on punishment after the fact and comparatively rigorous protections of rights. Though many states previously provided for greater surveillance and investigatory power in cases involving national security threats before 9/11, the criminal law model served as the predominant model for states in the fight against terrorism before then. But the existential threats posed by twenty-first century terrorism caused nation-states to adopt more aggressive preventative measures that blur the line between war powers and the powers of criminal law enforcement, and that challenge accepted notions of the rules of war because of the contested legal status of terrorists. Such measures have included treating captured terrorists as enemy combatants (rather than as criminal suspects or as normal prisoners of war) who may, therefore, be tried in military tribunals rather than in civil courts; employing more aggressive interrogation techniques in order to obtain intelligence that can prevent a major attack; detaining suspects indefinitely despite the lack of definitive evidence that they are enemy combatants who have violated the rules of war; and expanding the powers of surveillance (Bobbitt, 2008; Hoffman, 2006). Because liberal democracies exist to protect the security and rights of citizens, the battle against contemporary terrorism poses a special problem regarding what scholar Amos Guiora (2005) calls the 'balancing dilemma' between security and rights.

The emergence of twenty-first century terrorism has exacerbated the 'balancing dilemma' because of terrorism's distinctive qualities mentioned previously, and because of the previous growth of international law's commitment to human rights, also discussed earlier in this article. (See, e.g., Geneva Convention Relative to the Treatment of Prisoners of War, arts. 4, 13, August 12, 1949, 6. U.S.T. 3316, 75 U.N.T. S. 135.) Different liberal democracies have responded to the threat of market state terrorism in their own ways, based on such factors as their own understandings of national interest and their own political and legal cultures. Nonetheless, we can discern predominant trends. States typically expanded their powers to promote security, yet modified such powers over time in response to judicial and political pressures, and as more security was attained, however, precariously. In one respect, this trend supports the tenets of 'political realism' in foreign affairs and international relations: states will protect their sovereign interests when they feel they must, including readjusting the balancing dilemma (Posner and Goldsmith, 2005; Morgenthau, 1963).

For example, in the United States, federal courts have upheld detention of terrorists, military tribunals, and new surveillance while also requiring due process protections that the government had not provided (Chesney and Goldsmith, 2008). And in response to public and judicial pressure, the US government abandoned the use of the 'enhanced interrogation techniques' it had originally deployed. Israeli courts affirmed the Israeli government's declaration that it was engaged in armed conflict with Palestinian terrorists in 2000, thereby allowing Israel to engage in proportionate violent attacks against them (*State of Israel v. Marwaan Barghouti*, 2002). The Israeli Supreme Court also upheld the state's right to erect a 385-mile fence along the 'Green Line,' but ordered the state to minimize its effects (*Beit Sourik Village Council v. The Government of Israel & the Commander of the IDF Forces in the West Bank*, HCJ, 2056/04). Meanwhile, India redefined terrorism and expanded its powers of investigation and criminal process after 9/11, but courts constrained these powers in the face of public criticism (Guiora, 2005). As of this article, the balancing dilemma continues to be negotiated.

Civil Religion

This article is a revision of the previous edition article by R.K. Fenn, volume 3, pp. 1874–1878, © 2001, Elsevier Ltd.

Abstract

The concept of 'civil religion' suggests that a pervasive, nonsectarian understanding of morality and transcendence sacralizes the nation-state, the polity, and the history and destiny of a society. The concept became popular in social science circles following Robert Bellah's (1967) article. Civil religion has generally been credited with functioning as a source of cohesion and coherence in political life. However, recent empirical and theoretical developments have undermined the notion that civil religion is inherently an expression of social solidarity. We first explore definitional distinctions in the literature on civil religion, focusing on the United States, where the concept became important for understanding 'American exceptionalism' with regard to religiosity. We then turn to three developments that complicate the use and application of the civil religion concept as initially formulated: increasing religious pluralism, increasing religio-political polarization, and cross-national comparisons.

The concept of 'civil religion' suggests that a pervasive, nonsectarian understanding of morality and transcendence sacralizes the nation-state, the polity, and the history and destiny of a society. In the American context, where civil religion first gained popularity as a social scientific concept, it was posited to mean the vaguely Judeo-Christian beliefs and practices that provided cohesion and coherence to political life (Bellah, 1967). The question implicit in discussions of civil religion is how the state and religion are connected. In societies where the ruling apparatus is officially 'sacred,' this is fairly straightforward: the rulers are imbued with a divinity or divine sanction that grants them legitimacy. In ostensibly secular or religiously diverse societies, however, the relationship between religion and the state is less clear. Additionally, in societies in which a secular state rules a highly religious populace, the source of institutional legitimacy becomes a salient question, particularly when high levels of religiosity are accompanied by high levels of religious diversity, as in the United States. The concept of civil religion posits an answer to these questions: legitimacy comes through the development of a religious culture that provides solidarity, meaning, and collective identity that are more national than sectarian.

The theoretical discussion that has unfolded around the topic of civil religion for the past 40 years, however, has expanded, challenged, and reworked this assertion in a number of ways. In his seminal essay on the topic, Robert Bellah (1967) suggested that "from the earliest years of the republic [there has been] a collection of beliefs, symbols, and rituals with respect to sacred things … institutionalized in a collectivity," which he termed 'American civil religion.' The phrase 'civil religion' was borrowed from Jean-Jacques Rousseau, the influential eighteenth-century political philosopher, who suggested a top-down, sacred morality imposed by the state on its citizens (Demerath and Williams, 1985; Luchau, 2009). Rousseau was less convinced than either English 'social contract' theorists or his French Enlightenment colleagues that reason and self-interest would be adequate to hold together a society – particularly to bind the masses to the state. He saw the need for some sort of religion, albeit one freed from the patriarchal and monarchal ties that supported the *ancien regime*. Thus, he called for "a purely civil profession of faith, the articles of which it behooves the Sovereign to fix … a body of social *sentiments* without which no man can be either a good citizen or a faithful subject" (quoted in Demerath and Williams, 1985: 155).

Bellah, however, developed his concept owing more to Durkheimian notions about religion as integrative and unifying (Demerath and Williams, 1985; Fenn, 2001; Santiago, 2009). He envisioned American civil religion as something emerging in civil society from the national experience itself, rooted in the nation's religious inheritance but developing separately from it. Nonetheless, despite the differences in Bellah's and Rousseau's understandings of civil religion's sources, they both assumed that culture, in this case religious culture, creates solidarity. Further, they both articulated civil religion as symbols, rituals, and sentiments that evoke loyalty and unity, rather than theology or dogma per se. However, the ongoing debate around the concept of civil religion has undermined the notion that it is inherently an expression of social solidarity. In this article, we will first explore definitional distinctions in the literature on civil religion, focusing on the U.S. context, where the concept became important for understanding American exceptionalism with regard to religiosity. We then turn to three ongoing areas of debate within the field that complicate the use and application of the civil religion concept as initially formulated. We conclude by offering suggestions for the future of work on civil religion that consider these areas of debate.

Definitional Debates

The idea of American civil religion as conceptualized by Bellah quickly proved theoretically useful for understanding faith and politics in the United States, but the concept also generated a great deal of controversy (Wimberley and Swatos, 1998). This is not surprising given the political and cultural changes that the United States was experiencing in the late 1960s and 1970s. The wide-ranging discussions over what, exactly, civil religion is eventually led Bellah himself to lament the concept's muddied analytic usefulness (Bellah, 1980).

Luchau (2009), in fact, has suggested that there are as many definitions of civil religion as there are scholars discussing it. This panoply of definitions renders a clear or essentialist definition of civil religion somewhat challenging, as there is no shortage of concepts to sift through. As early as 1974, Richey and Jones identified five types of civil religion in the literature on the topic: (1) folk religion, (2) religious nationalism, (3) democratic faith, (4) Protestant civic piety, and (5) the transcendent universal religion of the nation (14–18). Of these types, Bellah concentrated on (5), leading much early research that focused on elaborating and demonstrating that particular understanding (see Gehrig, 1981; Hammond, 1980). For example, John A. Coleman (1970), following Bellah, defined civil religion as "the set of beliefs, rites, and symbols which relates a man's role as citizen and his society's place in space, time, and history to the conditions of ultimate existence and meaning" (70). Also in 1974, Martin Marty identified two, broader poles in the understanding of civil religion: 'the nation under God' and 'the nation as self-transcendent.' He identified these dominant understandings of civil religion with the 'priestly' and 'prophetic' strands that Weber (1922/1993) identified in religion's stance toward worldly social arrangements. In the years after Bellah's seminal piece, two things were clear: civil religion had gained traction as a concept but also engendered a multitude of definitions and uses.

Given this definitional variation, perhaps it is easiest to start with what civil religion is *not*. Civil religion is not simply public expressions of religion (Roof, 2009). Merely saying a prayer in public without any sense of connecting the nation to the divine in some way does not qualify as what the current literature understands as civil religion. Additionally, purely sectarian religion doesn't qualify as civil religion (Cristi and Dawson, 2007; Demerath and Williams, 1985). Civil religion is more abstractly defined than most denominations, faiths, or creeds. Rather than suggest 'Methodism,' 'Judaism,' or 'Catholicism,' civil religion is more likely to invoke broadly Judeo-Christian understandings about morality, history, and transcendence. Finally, civil religion is not the 'idolatrous worship of the state' (Bellah, 1992: ix). It represents the state being given legitimacy through the divine rather than turning the state into something divine in and of itself.

Turning to what theoretical understandings of civil religion share, civil religion is generally used to refer to a sense of transcendence and 'overarching religious values' (Porterfield quoted in Hammond et al., 1994: 9) that connect "the society's principles of legitimacy … with divine – or otherwise ultimate – realities" (Moseley quoted in Hammond et al., 1994: 18). While Bellah specifically understood civil religion as involving reference to the nonoffensive presence of a divine being (i.e., God) and as serving an integrative role for society, these specific elements of civil religion have become less important to more recent conceptions (Luchau, 2009). Cristi and Dawson (1996) suggest that understandings of civil religion, at least in the American context, tend to view civil religion as 'existing quasi-independently' of both the state and church, focusing on a sacralized 'set of core values, like liberty, justice, charity and freedom,' being 'carried' by various rhetorics and rituals of the American polity and people.

While there has been more definitional debate around civil religion than attempts at empirical verification of the concept, some empirical work does exist. Ronald Wimberley and colleagues (Christenson and Wimberley, 1978; Wimberley, 1976; Wimberley et al., 1976) provided statistical evidence for the notion that Americans share what could be called civil religious ideas. These studies found agreement across large swaths of the population with statements such as "America is God's chosen nation," "the flag of the United States is sacred," and "holidays like the Fourth of July [are] religious as well as patriotic" (Wimberley, 1976: 343). While later research (Christenson and Wimberley, 1978) complicated the picture by finding that generally religious individuals as well as members of certain religious groups were more likely to express civil religious sentiments than others, the evidence indicated that the widespread agreement with statements such as the above suggested that some kind of civil religious understanding did, in fact, permeate U.S. culture. In sum, civil religion is the generally nonsectarian, semi-independent expression of transcendence that connects the history, values, political institutions, or practices of a nation to some kind of understanding of ultimate reality, meaning, or divinity. It has traditionally been assumed to be unifying, although this has become less common in recent formulations. Additionally, available evidence finds that we can measure civil religious attitudes as correlated with but not dependent on faith tradition and religiosity, suggesting that it holds a position of at least some autonomy from sectarian religious expressions.

Recently, scholars interested in refining Bellah's concept for further use have increasingly asked how applicable any conception of civil religion can be that fails to address or account for three things: (1) the growing diversity of American society, (2) the continued political and religious polarization of the American population, and (3) the utility of the concept outside of the American context that Bellah originally intended it to serve. In this article, we examine foundational and recent work on the concept of civil religion with an eye toward how these three concerns have driven understandings of the concept and should steer future research.

Empirical and Theoretical Developments, Part 1: Diversity and Pluralism

Work on American civil religion has generally revolved around attempts to theoretically situate and refine the concept (Bellah, 1992; Cristi and Dawson, 2007: 273; Porterfield in Hammond et al., 1994), and, contemporarily, much theoretical work rests on what the diversity of American society means for the concept of civil religion. American religion has seen increasing pluralism with regard to ideology, faith tradition, practice, and increasing amounts of secularism and irreligiosity (Putnam and Campbell, 2010; Kniss and Numrich, 2007; Roof, 1999; Wuthnow, 1988). It has become a challenge for scholars to contend that civil religion is a single, unifying idea or set of values in the face of such great diversity of belief and practice.

Religious pluralism, additionally, is not neutral; social groups understand religious pluralism differently and thus put forward competing visions of what contemporary civil religion in the United States looks like. Mark Silk (2007), for example,

presents evidence that approaches to pluralism in the United States are regional, with what it means to be 'pluralistic' differing greatly in both application and appreciation based on social context. While Bellah's original conception of civil religion posited certain understandings of the core elements of American national identity, contemporary work is more likely to point to divergent visions of national identity that are used as cultural resources in conflicts over meaning in a pluralistic society (Cristi and Dawson, 2007; Fenn, 2001; Lichterman, 2008; Long, 1974; Porterfield in Hammond et al., 1994; Williams, 1999). Richard Hecht (2007), in fact, suggests that we have seen a shift from what he terms 'passive pluralism,' the form of pluralism of the mid-twentieth-century United States documented by Will Herberg (1955/1983), to 'active pluralism,' where diverse groups seek full participation while maintaining their unique identities.

Questions about what pluralism means for civil religion have, therefore, become central to the debates about the concept's usefulness. Robert Wuthnow (2004), for example, has suggested that a central question for understanding American civil religion must inherently be how our conceptualization of civil religion will change as increasing numbers of immigrants enter the United States, bringing religious ideas from Buddhist, Hindu, and Muslim contexts with them. It is not, Wuthnow contends, merely that there are more people practicing different faiths in the United States. Rather, it is the 'kind of cultural awareness' that comes with a religiously pluralistic society that drives the changing conception of American civil religion (161). Sarna (in Hammond et al., 1994), likewise, suggests that we continue to see "deep-seated cultural differences that … set Americans at odds with one another" with regard to the expression of religion, complicating how civil religion may be publicly exercised (21).

Bellah understood civil religion as a cultural container that made cohesion possible in the United States despite great diversity. This diversity, however, was largely within the traditions of Judeo-Christianity. The increasing pluralism of American society has posed new questions for contemporary understandings of civil religion. While the directions that American civil religion will take as the divergent conceptions of faith and divinity are incorporated into U.S. culture remain unclear, this pluralism creates the space for critical examinations of what national identity means in a contemporary context. New empirical testing is required to understand if and how expressions of civil religion continue to have unifying logic, and for whom.

Empirical and Theoretical Developments, Part 2: Polarization

The increasing pluralism of the United States anticipates a second concern in parsing out work on civil religion: any understanding of American civil religion must contend with ideological polarization. Recent work has found that Americans have become more ideologically divided during the last several decades, suggesting that the notion of a purely integrative civil religion cannot be squared away with empirical reality, if it ever could (Pew Research Center, 2012). While there has been evidence that civil religious ideas are widespread in the United States (Christenson and Wimberley, 1978; Wimberley, 1976), a belief that polarization may complicate what civil religion means has led researchers to develop a number of different conceptual handles seeking to explain how civil religion may continue to be useful given that its initial formulation suggested consensus. These formulations tend to agree on several key elements: (1) civil religion does continue to be a useful concept; (2) civil religion cannot be thought of as a single, static 'thing,' given the diversity of expressions of it in contemporary society; and (3) the diversity within civil religion is best understood not as a dichotomy but as a continuum that represents different ideological expressions of it.

Widespread agreement that civil religion is a continuum, however, does not lead to widespread agreement about what constitute its poles. Generally speaking, theorists tend to posit poles that largely follow Martin Marty's (1974) discussion that contrasts American priestly civil religion, which suggests that America is a special, sacred nation, with American prophetic civil religion, which suggests that the nation must live up to certain standards or be held accountable. Cristi and Dawson (2007) see enough congruence among different models of civil religion, including Marty's, Wuthnow's (1988), Davis's (1998), and Angrosino's (2002), that they have collected the various models and discuss a 'priestly, orthodox, and conservative account of civil religion' that celebrates nationalism, capitalism, and the United States as a nation of divine providence set against a 'prophetic, progressive, and liberal vision' that demands the United States live up to sacred values lest it face judgment (275).

These are not, however, the only ways that theorists understand the continuum upon which civil religion slides. For example, rather than focus on the 'content' of civil religion, Luchau (2009) focuses on the ontological aspects of civil religion. He draws on Göran Gustafsson (1984) and Demerath and Williams (1985) to suggest that there are two main poles of civil religion: civil religion as phenomenon and civil religion as rhetoric. Civil religion as a phenomenon assumes a values consensus in society and suggests that these values are integrated into the morality of individuals, while civil religion as rhetoric suggests the contested use of symbol systems for public consumption and political debates. Luchau suggests that we have moved away from civil religion as phenomenon to rhetoric, suggesting a move from consensus to competition with regard to values and symbols.

Additionally, we may understand civil religion and polarization with regard to how top-down or bottom-up it is. Williams (1996) suggests that religion in political mobilization can be viewed as 'ideology' (top-down) or 'culture' (bottom-up), and understanding civil religion as one or the other posits a specific understanding of the relationship of citizens to each other and to the state (see also Demerath, 2001; Cristi and Dawson, 2007). Demerath and Williams (1985) additionally point out that the original Rousseauian concept of civil religion was essentially tied to state power, suggesting that the Durkheimian notion of civil religion as an integrative aspect of a unified culture should not be taken as a given. While this understanding is not at the heart of Bellah's (1967) original conception of civil religion, it is not wholly absent. Bellah did understand civil religion as being salient during times of war and crisis (see Swatos, 2006, for a recent example of this

understanding). Marvin and Ingle (1996), in fact, suggest that a civil religion demands the sacrifice of its own through war to maintain its legitimacy. While patriotic rhetoric suggests that war is to destroy an enemy, what actually binds a people is the shared sentiment around the sacrifice of their own. In this way, civil religion is soaked in ritualized bloodletting. In sum, while there is broad agreement that civil religion is expressed in a variety of ways in a polarized nation, and there is implicit agreement that these poles represent wider cultural understandings around political ideologies, the exact meaning of the civil religion continuum continues to be up for debate.

Empirical and Theoretical Developments, Part 3: The Global Context

While Bellah's initial conceptualization specifically discussed 'American civil religion,' researchers have increasingly sought evidence of its existence outside of the United States. Important to the definitional debate is whether civil religion is predicated on the Judeo-Christian cosmos that has been dominant in American culture or whether other ideologies and religious systems, such as Confucianism, operate similarly (Cha, 2000). It may be that officially secular nations develop a sort of civil religion; conversely, having a connection to traditional sectarian religion may be necessary (Lowe, 2001). Researchers have taken up these questions with regard to a number of different social contexts, with varying results.

This research has used a variety of creative approaches. West (2008), for example, studies 'international civil religious pilgrimage' to draw conclusions about how such visitations shape national collective memories. In particular, he examines Australians, predominantly young backpackers, as they visit the Gallipoli battlefields, experiencing both a heightened engagement with a legitimizing myth (Hammond in Hammond et al., 1994) of their nation and a sense of disruption from being presented with a Turkish point of view. In this way, visitation of sacred civil sites can create a complex range of understandings when presented with a variety of national viewpoints. At its core, however, West's work assumes a sense of transcendence associated with the site of pilgrimage, for more than one people.

The notion that civil religion does appear in a variety of national contexts is borne out by additional comparative evidence. Flere and Lavric (2007) find quantitative evidence that civil religion exists in a variety of national contexts by comparing survey results from various Eastern European populations to results from the U.S. state of Alabama. They found that feelings of civil religion are connected to general religiosity and support for traditionalism, but that a sense of civil religion exhibits at least some impact independent of general religiosity and traditionalism across their various samples. This suggests some kind of cross-national understanding of civil religiosity. Lowe (2001) compared expressions of civil religion in the highly religious United States with those in the explicitly atheist Soviet Union and found many similar expressions, including a transcendent collective memory, cults around national heroes, sacred writings, rituals reinforcing the social order, and civil religious virtuosos. Lowe suggests that the U.S. and Soviet cases provide support for a Rousseauian understanding of civil religion in that both nations promoted self-sacrifice and unity, but it also suggests that the Soviet Union was closer to the top-down imposition of state legitimation than the United States.

Similarly, Cristi and Dawson (1996) find evidence for understanding civil religion as coercive in their analysis of Chile under the Pinochet regime. Pinochet, they argue, attempted to impose a civil religious discourse on Chilean society, casting himself in a priestly role with regard to an ethic of war and patriotic sacrifice. Drawing on established religious symbols in Chilean society and given legitimation via the Catholic Church (at least early in Pinochet's regime), Pinochet sacralized the fight against Marxism into a holy war, legitimizing political absolutism. Ultimately, Cristi and Dawson argue, Pinochet's attempts to create this civil religion from the top down were unsuccessful for a variety of reasons, leading them to suggest that analysis of situations in which civil religions succeed, fail, change, or stay the same may generate useful data and theoretical insight. Davie (2001), for example, suggests that increasing religious diversity in Europe is creating more salient national boundaries around lines related to Christendom, even in generally secular settings. This work, taken together, suggests that not only are concepts of civil religion applicable in contexts outside of the United States, but also some of the concerns we see about American civil religion, such as increasing pluralism and concerns over whether civil religion is integrative or coercive, play out in other national settings as well (Hefner, 2001).

The Future of Civil Religion Research

The sheer volume of work on civil religion indicates that researchers continue to find the concept theoretically useful. Few other concepts so evocatively capture the sacred place that national foundational heroes, institutions, values, and practices so often hold with the populace. However, the debates discussed in this article – that the civil religion concept must be theoretically reworked to encompass diversity and polarization as well as be modified for use outside of the United States – have created somewhat muddied waters, with a number of different theoretical assertions and positions vying for dominance. We conclude by offering some suggestions for future ways in which the concept may be refined and tested.

If the work discussed in this article is any indication, there appears to be agreement that civil religion is most useful when understood pluralistically, as something that represents both unity and coercion – an inclusive vision and an exclusive proclamation. Work on civil religion in the American context has tended to examine elite understandings of large historical events. Bellah (1967) himself suggested that civil religion was most apparent during times of trial such as the Revolutionary War, Civil War, and Vietnam War, and looked to how presidents used the divine in their inaugural speeches. If, however, we accept that civil religion may not be exclusively unifying, perhaps looking to elites may not always be the most fruitful way to study the phenomenon or its discourse. Rather, looking at how citizens' groups and social movements draw upon religious rhetoric as they put forward competing visions of society may serve to provide

useful empirical evidence for understanding the competing visions of national identity and its construction (Williams and Alexander, 1994). We might term this 'lived civil religion.' Works by Paul Lichterman (2005, 2008), Mark Warren (2001), and Richard Wood (2002) have explored many ways that religion explicitly enters the activism conducted by faith-based citizens' groups, while Courtney Bender (2003) has examined how a sort of generalized religion often undergirds the work done by volunteers at a nonprofit organization. These intermediate organizations, such as faith-based groups, nonprofit organizations, and social movement groups, are an important way that Americans learn how to understand and talk about civic culture (see Eliasoph, 1999). Additional work could uncover how various visions of national transcendence play into the positions taken by socially active organizations, both those that promote inclusivity or pluralism and those that promote exclusivity or a narrow understanding of who may count as a member of the national community.

Additionally, continued work at the international level could provide necessary scholarship on how the sacred works across cultural borders. Flere and Lavric's (2007) suggestion that there are civil religious understandings across national borders that are connected to traditionalism and general religiosity but not reducible to them is intriguing, and suggests possible avenues for analyzing how different cultures use concepts of the sacred. In particular, if civil religion may be understood as something that can be (1) coercive, (2) top-down, and (3) a failure if met with resistance from the populations it is being imposed on (Demerath and Williams, 1985; Cristi and Dawson, 1996), examining how different groups, both in and out of power, have manipulated sacred symbols and ideas to promote their agendas with varying degrees of success could help us understand how concepts of the sacred are used, disseminated, and modified more broadly. International work could, therefore, help us refine empirically what is at the core of 'the sacred' across a variety of cultural contexts.

Civil Rights

David Kairys, Temple University, Philadelphia, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Civil rights are legal protections of individuals or groups from certain forms of oppression that gained widespread acceptance throughout the world in the last half of the twentieth century and continuing into the twenty-first century. The origins of civil rights can be found in practices of governments or powerful individuals or institutions that came to be viewed as oppressive, although these are often obscured in foundational or origin stories that take on an abstract, timeless quality. The most common civil rights are prohibition of discrimination based on race, ethnicity, religion, and gender; the right to personal security, including protections for persons accused or suspected of crimes; the right to vote and to participate in democratic political processes; and freedom of expression, association, and religion. Civil rights lose their significance if they are not available to all people, but the failure to acknowledge conflicting rights and the interconnectedness of rights, interests, privileges, and expectations has made acceptance of civil rights advances more difficult than it has to be, particularly in countries where rights tend to be articulated in absolutist terms. The most troubling questions about civil rights have centered on which rights are protected, their content and formulation, and their enforcement. The model of judicial primacy in the United States produced two periods of historic protection of civil rights available to people of ordinary means, but no single source or enforcement mechanism for civil rights has proved consistently superior to others. Establishment and enforcement seem most effective when accomplished by popular and participatory means, and popular understanding of the importance and history of civil rights is probably the most significant factor in their continued vitality.

Civil rights legally protect individuals or groups from certain forms of oppression. While civil rights are commonly associated with the 1960s movement in the United States to establish equality for people of African descent and – more generally – with the US Bill of Rights, by the end of the twentieth century their reach and recognition was global. In modern political, academic, and public usage, civil rights embody, and provide legal support for, basic concepts of human dignity and respect for individuals and groups in their diverse cultures and ways. In the second decade of the twenty-first century, recognition and enforcement of civil rights, or some assortment of the most fundamental civil rights, are widely understood as a necessary element of freedom, democracy, and equality.

International bodies, treaties, and courts – and many countries – prefer the term 'human rights,' which usually encompasses a broader array of rights and places different priorities on some particular rights than does US civil rights law (*see* Criminal Liability and Criminal Defenses; Human Rights: Legal Perspectives; Civil Liberties and Human Rights). The United Nations Charter, the *Universal Declaration of Human Rights (1948)*, and many other human rights treaties and covenants, including recently the U.N. Declaration on the Rights of Indigenous Peoples (2007), protect social, economic, and cultural rights as well as political and civil rights (*see* Indigenous Rights). These rights often place affirmative obligations on governments to provide all their people with minimal nutrition, healthcare, housing, and education. Eleanor Roosevelt, criticizing the US reluctance to include economic and social rights, put it this way: "You can't talk civil" (see Copelon, 1998).

Civil rights are usually established in a written constitution, statute, or treaty. However, they have been based on unwritten constitutions and have occasionally arisen from the pronouncements of monarchs and conquerors, perhaps most famously Napoleon.

These sources of civil rights protections are not self-executing: some countries have strongly worded civil rights provisions in written constitutions that are not enforced; the meaning and interpretation of civil rights provisions are usually controversial; and despite the prevalence of civil rights aspirations and rhetoric, no country has as yet found a reliable method for systematic, consistent protection of civil rights.

Origins

The origins of some civil rights go back almost a thousand years to the earliest limitations on governments, which at least indirectly protected individuals. Civil rights as such emerged in the seventeenth and eighteenth centuries, as social development and political and philosophical thought emphasized the individual and, later, based national sovereignty and legitimacy on democratic forms of government. However, systematic legal enforcement, and even widespread aspirational recognition, of civil rights did not occur until after World War II. They quickly achieved global acceptance in the last half of the twentieth century; today the laws of almost all countries, and several widely adopted international pacts, at least purport to protect some array of fundamental rights of individuals.

Approached historically and contextually, the various civil rights can be traced to practices by governments or by powerful individuals or institutions that came to be viewed as oppressive. Thus, the Fourth Amendment to the US Constitution limiting police searches was a response to the dreaded house-to-house general searches by British authorities in the colonial period. However, such origins are often obscured, because civil rights – like other basic legal precepts – are usually analyzed and clothed with the rhetoric of foundational principles and tend to take on, in law as well as in politics and fiction, an abstract, timeless quality that transcends history, experience,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86009-2

and human agency. This occurred in the United States with freedom of speech, which has acquired a major place in the national origin story, although its most significant features developed in the mid-twentieth century by common forms of social change (Kairys, 1982; Levy, 1985).

Scope

The most common civil rights are equality based on race, ethnicity, religion, and gender; the right to personal security, including protections for persons accused or suspected of crimes; the right to vote and to participate in democratic political processes; and freedom of expression, association, and religion. Additional civil rights are emerging from political, legislative, and judicial processes in a range of countries and internationally. Privacy, which in the US system encompassing personal security and autonomy as well as control over personal information, is of growing concern throughout much of the world. The rights of indigenous peoples (*U.N. Declaration on the Rights of Indigenous Peoples* (2007)) and sexual preference minorities have recently gained substantial recognition.

Personal security was the first, and remains the primary, civil right. It was a major focus of leading Anglo-American legal authorities, from William Blackstone (1769/1992) and St. George Tucker (1969) to Thomas Cooley (1874). The pathbreaking civil rights text by Thomas Emerson and David Haber (1952) considers the right to personal security first and describes its significance in the introduction: "In a society based upon human dignity and the development of the individual personality, clearly all members are entitled to security of the person – protection from bodily harm, involuntary servitude, and the fear of physical restraint." Although the rights of criminal defendants in the United States are commonly thought to originate in the 1960s Supreme Court rulings, the US Bill of Rights has as its major subject and most numerous protections a series of limits on the government's power to punish individuals criminally.

Although the United States was an early standard bearer and innovator on civil and human rights, the current content of human rights around the world often exceeds or precedes specific US civil rights protections, including prohibition of the execution of children and mentally disturbed adults, protections against domestic abuse, and a range of social, economic and cultural rights. Other nations also place different relative importance on various rights, such as rejecting absolutist free speech rights and emphasizing equality rights (Movement Raelien Suisse vs Switzerland, 2012). While the United States has adopted most of the human rights treaties and covenants (although often with specific reservations), US courts have not consistently enforced them. The United States is also unusual among the nations of the world in its renewed and continuing embrace of capital punishment and in the retrenchment of procedural and fair trial rights to expedite executions.

In most countries, civil rights protect individuals from their governments, but protection for groups and from other individuals have also been recognized (Kichwa Indigenous Community of Sarayaku vs Ecuador, 2012). Prohibitions of slavery around the world limit individuals as well as governments. Equal rights for women have included limits on individually inflicted violence against women and recognition of the rights of women as a group. Group rights have also been recognized in some jurisdictions for indigenous peoples, ethnic minorities, children, and the disabled (*see* Indigenous Rights; Juvenile Justice: International Law and Children's Rights; Law and People with Disabilities).

Universal, Absolute, and Conflicting Rights

Civil rights lose their meaning and importance if they are not extended to all people. However, the universality of civil rights, both within a particular country and across national borders, and the common notion that extension of civil rights to those previously denied them has no effect on others are problematic.

Typically, recognition of civil rights disturbs a status quo in which privileges and hierarchies were entrenched. If previously silenced speakers or voters gain the rights to speak and vote, the effectiveness of the voices and votes of the previously privileged is diminished. Abolishing racial discrimination in employment or college admissions diminishes the prospects of the previously privileged. Abolishing racial discrimination in public accommodations diminishes the freedom of association of those who wish to exclude racially. Recognition of the rights of people who have been oppressed involves a determination that the interests, expectations, tastes, and sometimes civil rights of others constituted an illegitimate or disproportionate privilege which came only at the expense of that oppression, and to which they should not have been, and no longer are, entitled. The failure to acknowledge the interconnectedness of rights, interests, privileges, and expectations has probably made acceptance of civil rights advances more difficult than it has to be. This has been a substantial problem in the United States, where interconnectedness is only acknowledged for affirmative action and where civil rights tend to be articulated in absolutist terms.

Absolutist conceptions of civil rights usually rest on the same thinking, memorably critiqued by Justice Oliver Wendell Holmes' famous example of shouting 'fire' in a crowded theater. Words have effects, otherwise we might not be so fond of them, and in some circumstances those effects outweigh the value of speech. Such occasions are rare, but they do exist – for example, where one person's speech is interfering with or drowning out another's or all others. Nevertheless, the US Supreme Court has protected electoral campaign finances as speech in absolutist terms that make even minimal regulation difficult or impossible (Buckley vs Valeo, 1976; Citizens United vs FEC, 2010). The Court characterized money as speech, and refused to recognize as significant or legitimate countervailing concerns the importance of fair elections to society and other individuals or the speech rights of those whose voices cannot be heard in money-driven elections.

Absolutist conceptions of this sort, though often articulated by staunch advocates of individual rights, are reminiscent of the 'Lochner era' in the United States, in which the civil right to due process was used by the Supreme Court to invalidate a series of economic reforms aimed at protecting working and poor people. The combination of an absolutist formulation and a civil right based on unrestrained free enterprise yielded

one of the most notorious eras in US constitutional law. These rights that people around the world seek and rely on for protection from powerful individuals, groups, and institutions, often at considerable personal sacrifice, can become another instrument for the powerful (Kairys, 1993, 2013).

There is also a fundamental sense in which all civil rights protect individuals by limiting others – either all others collectively, because civil rights prohibit certain actions by majorities and governments, or individually, in the situations in which civil rights protect against private as well as governmental actions. Thus, civil rights both bestow and limit freedom. They limit the ability of even democratically constituted governments, for example, to discriminate against a racial minority or to ban an opposition political party, by placing the individual's or minority's rights above collective power (West Va. Bd. of Educ. vs Barnette, 1943). Civil rights are, in this sense, both a limit on and a necessary feature of democracy.

These tensions permeate heated controversies about the universality of civil rights across national borders. The conventions on the rights of women referred to above have been the subject of an unusual array of national reservations, usually on the ground that they clash with cultures and religions, which also can claim civil rights protection. For example, the UN General Assembly has called on countries to eliminate female genital mutilation because it violates several of the most fundamental and generally accepted civil and human rights, although it is mandated by some cultures and religions.

Formulation and Enforcement: The US Model

The US tradition of extensive judicial power, which includes judicial innovation beyond the specific language of a constitution, statute, or treaty, is gaining some acceptance internationally. This expanded acceptance is in part due to its reputed tendency to protect civil rights, although the role of courts in civil rights matters (and more generally) is controversial in the United States. Many other countries have tended to rely on international human rights treaties or legislation. Courts lack the democratic legitimacy of legislatures, while their very distance from democratic processes could enhance the potential for protection of individual rights against even mobilized majorities. Protection of individuals and groups from majoritarian oppression is the hallmark of meaningful civil rights and provides the best measure of a particular society's civil rights record. A closer look at the history and record of a particular country – the United States, because of its historical role and wide recognition as a leader and model for civil rights – demonstrates both the potential and the difficulty of sustained, systematic protection of civil rights.

The role of courts in the civil rights victories of the 1960s and throughout US history is often exaggerated (Kairys, 1993, 2003, 2006; Cover, 1976). Integration of public schools (Brown vs Bd. of Educ. 1954) was a milestone, but most aspects of equality for African Americans in the twentieth century were established by the US Congress. In the 1960s these included banning racial discrimination in voting, housing, employment, and public accommodations. The major civil rights advances of the nineteenth century were achieved by constitutional amendment and legislation.

The history of US courts reveals them to be more often an obstacle to than a protector of civil rights. For example, the US Supreme Court ruled in 1857 that African Americans have 'no rights which the white man is bound to respect' and are not fully citizens or human beings (Dred Scott vs Sanford), which destroyed the Missouri Compromise on slavery and was a contributing cause of the Civil War; approved segregation even after the Civil War amendments to the Constitution (Plessy vs Ferguson, 1896); negated the 'privileges and immunities' clause of the Fourteenth Amendment (Slaughterhouse Cases, 1873), which applied civil rights protections against the states; refused to protect even the most basic free speech rights until the 1930s (Davis vs Massachusetts, 1897; Kairys, 1982); and approved the imprisonment of all persons of Japanese ancestry on the west coast during World War II without any charges or proof of individual guilt (Korematsu vs US, 1944). Generally, throughout US history, oppressed minorities and individuals facing repression by government or organized majorities – including in modern times the repressive McCarthyism of the 1950s – have not been significantly protected by the courts.

There are only two periods in US history characterized by systematic and sustained judicial protection of such civil rights, from about 1937 to 1944 and from about 1961 to 1973. Both these periods occurred in the context of sustained mass popular support and successful legislative initiatives for civil rights, which in the US system seem necessary (but not sufficient) for systematic protection. During these periods, the Supreme Court established a system of limited government and protection of individual rights available to people of ordinary means probably unrivaled in world history, including strenuous protection of speech, association, and privacy; procedural and substantive rights of persons accused or suspected of crime; the rights of women; voting and participatory rights; and prohibitions of discrimination (Kairys, 1993, 1998, 2006, 2013; W. Va. Bd. of Educ. vs Barnette, 1943).

The main judicial vehicle for protecting civil rights in these two periods was the 'strict scrutiny' standard of judicial review, by which any government action that infringed or restricted these rights was strictly scrutinized and presumptively invalid, surviving only if supported by a 'compelling' government interest that could not be furthered by 'less restrictive' means.

While these decisions seldom articulated absolute rights (although absolutist rhetorical flourishes were common), in practice strict scrutiny meant near certain invalidity.

Starting in the mid-1970s, as the national political mood changed and more conservative justices were appointed to the Court, the Supreme Court repudiated or significantly diluted almost all of the major civil rights advances of the post-World War II period. This retrenchment was led in the political arena by President Ronald Reagan and a conservative movement that emphasized limiting government and espoused the sometimes extreme distrust of government evident in many periods of US history (Wills, 1999).

The thrust was to empower the people by limiting the courts – in the popular phrase, 'judicial restraint' – which, paradoxically, strengthens government and weakens individual rights. Thus, this conservative judicial restraint trend reviled the 1965 case establishing a civil right to privacy (Griswold vs Conn.), a decision that protected the individual and the people generally from

a state law that banned all use of birth control. A judicially based system of protection of civil (or any other) rights requires the courts to intervene when government is infringing on protected rights, and conservative justices have not hesitated to intervene to protect civil rights they value (e.g., Buckley vs Valeo, 1976; Shaw vs Reno, 1993). Historically, the pattern in the United States has been advocacy of judicial restraint by those whose values and approaches are being rejected by the courts. Perhaps the most vehement and successful advocate of judicial restraint was liberal President Franklin Roosevelt, whose reforms were struck down by a Supreme Court intent on imposing unrestricted laissez-faire economics (Kairys, 1998).

In this retrenchment, the rights to exercise nonmainstream religion and against establishment of religion were substantially undercut, including the refusal to protect a Native American religious ceremony that pre-dates Christianity (Empl. Div. vs Smith, 1990). Speech rights available to people of ordinary means were retrenched (for example, the public areas and circumstances available for protest were substantially narrowed), while speech rights available to corporations and wealthy individuals were enhanced, including recognition of corporate free speech rights. The equality rights of minorities were undercut by adoption of virtually insurmountable burdens of proof, resulting in denials of relief for some egregious practices left over from segregation. The equality rights of the white majority were enhanced, resulting in successful challenges to electoral reapportionment and affirmative action, even where they were good faith remedial efforts to end discrimination against African Americans and other minorities. As a result, almost all the winning parties in racial equality cases decided by the Supreme Court in the last few decades of the twentieth century and continuing into the twenty-first were white. The US attempt to end centuries of discrimination that included slavery and forced segregation was short and mostly limited to erasing de jure discrimination; the mass of African Americans live in the same segregated poverty they endured under de jure segregation (Kairys, 1993, 2006, 2013; Memphis vs Greene, 1981; Richmond vs Croson, 1989; Shaw vs Reno, 1993).

This retreat was accomplished by a range of judicial means. In some areas, such as exercise of religion and some aspects of privacy, the Court withdrew strict scrutiny protection. In others, such as equality, establishment of religion, and some aspects of free speech, a range of new rules made it near impossible to prove a violation – such as the requirement for proving that government not only violated a civil right but did so purposely, with animus or the specific motivation to violate the right.

None of these new rules is required by the language of the US Constitution or by rules of legal reasoning or analysis; nor is the strict scrutiny standard that was used to protect civil rights. This is characteristic of the judicial model, which in the United States yielded cyclic protection of civil rights in some (not all) periods in which support for those rights had strong, sustained, and politically mobilized support (see Kairys, 1998, 2003, 2008).

By the end of the twentieth century, the lead in civil rights had passed from the United States to other nations and to international human rights tribunals and agreements. The Constitutional Court of South Africa led a worldwide trend to ban or limit the death penalty (State vs Makwanyane, 1995). The European Court of Human Rights protected the rights of gay men and lesbians (Dudgeon vs United Kingdom, 1981); the Supreme Court of the United States initially rejected such rights (Bowers vs Hardwick, 1986), then accorded them some protection (Lawrence vs Texas, 2003). The rights of racial minorities and women were advanced principally by international human rights agreements. Progress in this direction has come mostly as a result of international human rights agreements and the growing sense they represent that oppression and repression, though they have hardly ceased, are no longer internationally acceptable.

Prospects for Civil Rights

Since civil rights can encompass a variety of possible limits on government to protect individuals and groups (and some limits on other individuals and affirmative obligations of governments), the details of their substance, context, and history are necessary for an understanding of their social meaning and importance. In this sense, it is hard to say that any of us is 'for civil rights,' and perhaps harder to say we are 'against civil rights' (which might mean government without limits), without specifying whose rights, which rights, and the context. For some, government is most oppressive when it limits gun ownership or attempts to overcome the effects of past discrimination; for others, it is most oppressive when it limits exercise of religion, abortion rights, or the rights of historically oppressed minorities. In the post-World War II period, the United States set an international standard for protection of minorities and the enforcement of a range of civil rights that protect the individual from oppression by government and powerful majorities; but US history also demonstrates the fragility of civil rights, and the use of civil rights to insulate the powerful from popular reforms aimed at protecting working and poor people.

Civil rights have played an important role in the advancement of human dignity, respect for the ways of diverse cultures and individuals, and democratic forms of government. In a relatively short time in the last half of the twentieth century, racism moved from acceptable or trivial to wrong (Kairys, 2006), and a deep sense of civil rights and fair play became an international intellectual, moral and political standard. However, this has not stopped – by any reasonable measure – racial, ethnic, religious, and national oppression or violence, or the routine denial of the range of basic civil rights. There is a substantial and troubling divide between our words, aspirations, and moral precepts on the one hand, and our actions on the other. We may be a species whose gift of reason and empathy has outpaced its habits of survival, which still reside – as if helpless to listen to our own pleas – in deep-seated (perhaps significantly genetic) tribalism. If this is so, the struggle for civil rights and human dignity will be long, indeed, but all the more compelling.

No single source or enforcement mechanism for civil rights has proved consistently superior to others. Establishment and enforcement seem most effective when accomplished by the most popular and participatory means available, and popular understanding of the importance and history of civil rights is probably the most significant factor in their continued vitality.

Abstract

This article explores the importance of the US Civil Rights Movement (1954–68), which originated in the American South and used nonviolent direct action to confront Jim Crow laws and regulations in an effort to force the federal government to dismantle the system of racial segregation and inequality.

Black Oppression

As late as the middle of the twentieth century, millions of black citizens in the US were socially oppressed, economically exploited, and politically disenfranchised. These forms of subjugation persisted in a nation viewed as the world's leading democracy. This view of the US was projected nationally and internationally by American leaders. The image of the nation as a democracy contrasted sharply with its treatment of its African-American citizens. Unlike European immigrants, with the exception of forced migrants including the Irish in the seventeenth and eighteenth centuries (Jordan and Walsh, 2007), black Africans were abducted and forcibly transported to America. For a period of two and a half centuries, enslaved blacks supplied a significant portion of the labor that enabled America to become an economic power. Slaves were not merely denied basic rights, they were officially defined as chattel, non-human beings. In apportioning representatives to the individual states, they were counted as three-fifths of a person, but they had absolutely no legal rights themselves. Due to the treatment they suffered, they faced serious health issues and enslaved women were forced to work throughout pregnancy (Fogel, 1994), often endangering their own lives as well as their children's.

The economic and social gap between the states of the North and South reached a breaking point with the election of Abraham Lincoln to the presidency in 1861. Southern states seceded from the Union and war broke out between the two sections. During what came to be called the Civil War (1861–65), President Lincoln issued the Emancipation Proclamation freeing the slaves in the southern states. With the victory of Union forces in 1865, black equality became a real possibility. For a brief period, it appeared that former slaves would be granted rights as American citizens. During the Reconstruction period (1865–77), blacks gained citizenship rights including freedom of movement, restricted male access to the franchise, and access to employment. This was a promising beginning, but it would not continue for long.

In the late 1870s, a system of racial segregation and unequal treatment, known as Jim Crow, emerged with the express purpose of returning blacks to white control. Leon F. Litwack (1979) and others describe in detail how the new form of oppression required segregation of blacks and whites in virtually every public encounter. The races were not allowed to use the same hospitals, schools, hotels, waiting rooms, or barber shops and beauty salons, nor could they sit on the same side of a courtroom, or be sworn in as a witness using the same Bible. One black recalled in an interview (Chafe et al., 2001: p. 5) that as a boy whenever he left home his mother told him to be sure to drink enough water to last him for a sufficient period of time because he would endanger himself if he attempted to drink from a public 'white' water fountain. Perhaps the most contentious locus was public transportation, which first appeared at the end of the nineteenth century and for which there were no customary habits to observe. Moreover, blacks were excluded from the political process, which meant that the law and its enforcers were all white. Toward the close of the nineteenth century, the emerging system called 'Jim Crow' received backing from the highest court of the nation. In 1896 the Supreme Court ruling in *Plessy v. Ferguson* declared that racial segregation did not violate the US Constitution. The court ruled that it was legal to require the races to use separate-but-equal facilities. With this ruling, Jim Crow laws and ordinances became national in scope, although they were more rigorously enforced in the South.

By the middle of the twentieth century, the majority of blacks were disenfranchised. In the South, blacks held no significant political offices and were constant victims of terror and violence, including lynching. In the labor market, blacks were restricted to undesirable low-paying jobs and subject to the will of white employers. Beyond economic subjugation, African Americans experienced daily personal humiliation because racial segregation marginalized them as a people and labeled them as an inferior race. They were stripped of human dignity; simple titles of respect such as 'Mr' or 'Mrs' were withheld, and even white children held symbolic authority over all blacks, however elderly or eminent.

The Movement's Origin

From the earliest days of slavery, African Americans staunchly resisted their harsh treatment by whites. Attempts at coordinated, violent resistance such as the Stono Rebellion (1739), Demark Vesey's Rebellion (1822), and Nat Turner's Rebellion (1831) invariably ended in failure, punishment, and attempts by whites to further restrict black movement and freedom (Berlin, 1998). While these explosive incidents of resistance were collective and public, covert resistance was more common. Slaves disobeyed orders, broke tools, pretended ignorance, slowed work routines, escaped for various lengths

of time, and released their frustrations by singing spirituals and telling stories about the self-importance and superiority felt by white people. Alan Dundee (1990) offers a collection of traditional 'toasts' and examples of 'signifying' that skillfully penetrated white pretentions of superiority and allowed blacks to share their feelings of resentment.

Beginning in the early twentieth century, black leaders like Booker T. Washington, W.E.B. Dubois, and Marcus Garvey attempted in their respective ways to gain rights and respect for black Americans. Perhaps the most significant group formed in this period was the National Association for the Advancement of Colored People (NAACP), founded in 1909 (Sullivan, 2009). The modern Civil Rights Movement drew upon this tradition and embedded itself deeply within the historic struggle for black liberation.

The movement emerged where black oppression was most intense and where racial segregation was most firmly entrenched: in the Southern states. Given the scope of oppression and the power of the white opposition, the birth of a powerful resistance movement was unanticipated, especially by whites who thought that segregation was part of the natural order and that blacks accepted it as such. Several factors contributed to a determination on the part of blacks to change the status quo.

First, after returning from World War II, black soldiers who had risked their lives to free citizens of the Allied nations were determined to work for freedom and equality for themselves in their own country (Wynn, 2010). Second, by the 1950s large numbers of African Americans had migrated to southern cities where they developed tightly knit urban communities and dense, effective communication networks (Dodson and Diouf, 2005: pp. 134–153). These resources made it possible to mobilize people. Third, the NAACP won several legal cases against the Jim Crow system, most significantly the 1954 Supreme Court decision in *Brown v. Board of Education*, which reversed the 1896 *Plessy v. Ferguson*, which had judged segregation to be constitutional. The Brown ruling stated that separate schooling based on race was unconstitutional. The implications of this ruling went far beyond this case for it delegitimized the entire system of racial segregation and encouraged struggles to implement the court orders (Ogletree, 2004).

Additionally, changing international relations were important to the birth of the movement. Former colonies in Africa and Asia were attempting to gain independence and establish new governments. African Americans identified with those struggles, which intensified their own thirst for freedom. Moreover, the context of decolonization and Cold War rivalry rendered the US federal government susceptible to pressure from an oppressed black population because the country sought to persuade these new Third World nations to model themselves after American democracy, not the Soviet alternative. However, racial oppression stood as a barrier to harmonious relations between the US and the emerging Third World nations. The proliferation of television and communication satellites made it possible to show white brutality to blacks to a worldwide audience. America's participation in the two world wars and the Korean War also rendered it vulnerable to black protest, because in those wars the US championed egalitarian values. In this context, black soldiers were radicalized while fighting for democracy on distant shores (Wynn, 2010). Thus, the federal government came under increased and sustained international and domestic pressure to support efforts to overthrow institutionalized racial segregation.

Strategies, Tactics, and Goals

These factors created the fertile soil from which the Civil Rights Movement emerged. By employing the strategy of direct action, this movement mobilized widespread social protest. For such a strategy to succeed, black movements had to disrupt white communities, businesses, and institutions and prevent them from doing business as usual. To this end, civil rights leaders and organizers mobilized thousands of African Americans to confront the Jim Crow institutions through social protest.

The leaders of the Civil Rights Movement succeeded in mobilizing massive nonviolent social protest. Innovative tactics included economic boycotts, beginning with a year-long boycott of a bus company in Montgomery, Alabama, sparked by the arrest of Mrs Rosa Parks, in December 1955, and led by Rev. Martin Luther King Jr. Essential to this early boycott were black churches, which offered the only safe place to hold 'mass meetings' at which the black community could share information that was unavailable through newspapers owned by whites, make plans for action, and encourage one another through sermons, speeches, and group singing of traditional spirituals, hymns, and newly written protest songs (Sullivan, 2009).

The churches cooperated closely with black colleges in the organized sit-in demonstrations that spread quickly when four black college freshmen sat down at a lunch counter in Greensboro, North Carolina in February 1960. When they were refused service, they politely remained seated and refused to move. The next day they sat down at the same counter with the same result. While some have viewed the initial sit-ins as independent, spontaneous acts on the part of impatient college students who were breaking from previous civil rights activities, Aldon Morris (1981) contends that, to the contrary, these sit-ins were carefully considered and resulted from close cooperation between leaders in the colleges and the black churches that allowed the demonstrations to continue and spread rapidly to other store and to other cities. The student sit-in movement of 1960 was a crucial development in that it injected new energy into the Civil Rights Movement, pointing the way to the efficacy of mass participation at the local, everyday level.

The breadth of participation eventually reached down into the lower age groups when dramatic confrontations of schoolchildren with police and firefighters in the streets of Birmingham, Alabama, in 1963, brought serious media attention to the violence white officials were inflicting on peaceful demonstrators (McWhorter, 2001). The largest, most widely reported mass mobilization of supporters of the movement came in August 1963 in the March on Washington, which culminated in Dr King's "I Have a Dream" speech.

The goal of these protests was to overthrow racial segregation and empower African Americans by seizing the franchise. Southern officials utilized their institutional power and the resistance of the larger white community in an intense, and often violent, effort to defeat the movement and to maintain

legally enforced racial segregation. Movement participants – many of them women, children, and college students – were beaten and brutalized by white southern law enforcement officials, and thousands were arrested and jailed for their protest activities. Others paid with their lives, including NAACP Mississippi field secretary Medgar Evers, who was assassinated in 1963 (Evers-Williams and Marable, 2005), and three civil rights workers who were killed near Philadelphia, Mississippi the following year. Nevertheless, the widespread and highly visible confrontations in the streets, which contrasted the brutality and the inhumanity of the white segregationists with the dignity and resolve of black protestors, made the cause of black equality the major issue in America for over a decade. The nation and its leaders were forced to decide publicly whether to grant African Americans their citizenship rights or to side with white supremacists and the undemocratic subjugation of African Americans.

National Achievements

The movement could not be dismissed. Eloquent leaders and their massive followings sustained the pressure on local elites and the federal government. Countless heroic figures inspired and organized a massive following. Among them were Rosa Parks, a dignified older woman and local NAACP activist, who sparked the Montgomery bus boycott when she defied an order to move to the back of the bus to the 'colored seats'; Martin Luther King, Jr., who emerged from the Montgomery bus boycott and the Southern Christian Leadership Conference (SCLC) to assume a position of preeminent moral leadership and national influence; James Forman, executive secretary of the more militant Student Nonviolent Coordinating Committee (SNCC), who was to challenge SCLC's and King's strategy; SNCC's leader, Stokely Carmichael (later Kwame Toure), who introduced the slogan 'Black power'; James Farmer and Floyd McKissick who led the Congress of Racial Inequality (CORE); and Fannie Lou Hamer, a sharecropper who went to a voter registration meeting run by SNCC, was arrested at the courthouse of Indianola, Mississippi, when she tried to register to vote, and then was viciously beaten in prison. Hamer, along with Parks, personified the thousands of women who played important roles in organizing and leading the movement.

These leading figures and thousands of movement participants articulated black suffering and the democratic aspirations of African Americans of every generation and circumstance. Thousands of whites (students, ministers, lawyers, and other civil rights workers) were inspired to participate in the Civil Rights Movement in various ways. Doug McAdam (1986, 1988) describes activities such as signing a petition supporting civil rights as 'low-risk/cost activism.' He examines how motivation for activism and a sense of membership in a group come into play in determining the amount of risk an individual is willing to take on in such a movement. His examination of those who elected to participate in the 1964 Mississippi Freedom Summer Project, a campaign that involved hundreds of volunteers in voter registration drives and the creation of 'freedom schools,' delineates some of the characteristics of participants like Andrew Goodman and Michael Schwerner who were willing to become 'high-risk/cost' activists and eventually lost their lives.

Differences regarding ideology, leadership style, and goals emerged within the movement as the SCLC, NAACP, SNCC, CORE, and other organizations reached different judgments about the effectiveness of nonviolent action, the desirability of racial integration and separatism, the role of whites in the movement, and the influence of black nationalism. Despite these controversies, the moral challenge and the widespread social disruption caused by the economic boycotts, the marches, the sit-ins, and other forms of nonviolent direct action, coupled with the international pressure, created an impasse in the nation that had to be resolved.

As a result, the Civil Rights Movement achieved important legislative victories in Congress. The landmark Civil Rights Act of 1964 outlawed discrimination in public accommodations on the basis of race, color, religion, or national origin and it identified the legal measures to be used to achieve racial integration. Moreover, it barred discrimination in employment practices on grounds of race, color, religion, national origin, or sex.

The passage of the 1965 Voting Rights Act significantly eliminated the use of literacy tests, authorized the attorney general to challenge the constitutionality of poll taxes, and introduced procedures that provided for the appointment of examiners to ensure that all restrictions on black voter registration be ended. In short, the Voting Rights Act enfranchised the southern black population, making it possible for a historic black elected political class to emerge.

International Achievements

The significance of the Civil Rights Movement extends far beyond its historic overthrow of the Jim Crow laws. The movement has affected US politics in fundamental ways. It demonstrated to the oppressed black community how concerted effort could be successful, and it made social protest respectable. The Civil Rights Movement also proved that social protest is capable of generating significant change. Hence, the movement broadened the scope of US politics and inspired diverse movements for citizenship rights and social justice in the US and abroad. Before the movement, many groups in America – including women, Hispanics, Native Americans, farm workers, the physically disabled, gays, and lesbians – were oppressed but unaware of how to resist or galvanize support. The Civil Rights Movement provided a model of successful social protest and produced a host of new tactics and social change organizations. Moreover, the movement influenced freedom struggles around the world. Participants in freedom struggles in Africa, Eastern Europe, the Middle East, Latin America, and China have made it clear that they were deeply influenced by the US Civil Rights Movement.

Continuing Challenges

For all its success and influences, however, the Civil Rights Movement did not solve all of America's racial problems. In the second decade of the twenty-first century, despite a black American being elected to the presidency, many African

Americans and other non-white groups are still at the bottom of the social and economic order. These current conditions are exacerbated by a social climate in which the disadvantaged are often blamed for their own predicament. Thanks to the Civil Rights Movement, a relatively large black middle class has emerged. Yet, over a third of the black community remains trapped in poverty (Wilson, 2009; Klinker and Smith, 1999; Joseph, 2010). Black Americans are disproportionately the victims of police brutality and housed in the rapidly growing prison industry. Thus, some blacks enjoy middle-class comforts while millions of others are victims of lack of opportunity, hopelessness, and high rates of imprisonment. Poverty and inequality are also widespread outside the black community. It may be that organized protest remains the only viable means to achieve greater empowerment. If this is the case, the Civil Rights Movement has left a rich legacy to inspire and inform future struggles. The sparking of a renewed interest in the academic study of resistance and social protest is an unnoticed legacy of the Civil Rights Movement. Through such studies it is possible that new mechanisms of social change will come to light.

Civil Service

Abstract

The civil service is the generic name given in English to the administrative apparatus of the state. Historically, bureaucratic administrations were developed in Egypt and China to serve the rulers, or the dynasty. These bureaucrats were engaged in activities such as land registration, water allocation, tax collection and above all managing war-related affairs. The emergence of the *modern* civil service is directly connected to the crystallization of the European-style state. A professional, career civil service (based on entrance examinations) was first introduced in Prussia and France and subsequently in Britain and the United States. In democratic states, the professional civil service is assumed to exist as a differentiated and mostly politically neutral institution. By contrast, in nondemocratic regimes the public bureaucracy operates sometimes from the ruler's palace, the military barracks, or the party's headquarters. Civil servants are in charge of many different activities that can be grouped under three headings: shaping and implementing public policy; providing services to individuals, groups, and organizations; and administrating regulatory schemes. These areas of responsibility shift over time. In the 2000s, the modern version of the state is changing and the size, structure, and functions of the civil service are in transition and transformation. Independent public and private entities and agencies are performing what used to be civil service tasks. Other functions have been privatized or 'outsourced' and if a 'skeleton state' will emerge, it may shatter many of the old features of the classical civil service model. Furthermore, new forms of collaborative governance have emerged, which bring together civil service departments and a range of private and voluntary organizations, causing the boundaries between the sectors of government, civil society, and business to become increasingly blurred.

Introduction

The civil service is the generic name given in English to the administrative apparatus of the state. The term was first introduced in the British administration in India and then in the UK (1854), and has become almost universally synonymous with civilian (i.e., nonmilitary and nonjudicial) administrators employed by central governments. The civil service is also referred to by different terms (e.g., 'public bureaucracy'), and it differs from other bureaucracies by virtue of its public missions, however defined. It has a collective justification, namely, doing something otherwise unattainable for a certain public end, and therefore, civil servants have been entrusted with the task of being the guardians, or at least the interpreters, of the common good. Another term loosely used is 'the public sector' as distinguished from the private (business) sector. It may include all the not-for-profit organizations, governmental and nongovernmental, as well as local and regional authorities. The modern civil service is above all a 'state institution' and this article will focus on the changing relationship between the state and its specialized bureaucratic institution – the civil service.

History

There were bureaucratic administrators long before they were known as 'civil servants.' Historical antecedents can be found mainly in centralized states and empires where public bureaucracies were developed to serve the rulers or the dynasty. Despite their subservience to the emperors and kings, however, these bureaucracies became 'professional,' that is, they manifested some conception of themselves as servants of the 'state,' the polity, or even the community (Eisenstadt, 1965). Such embryonic civil service institutions existed in different forms first in the Egypt and China ancient empires, and later, for instance, in the Byzantine, Sassanid, Abbasid, and Ottoman empires. Sculptures of the ancient Egyptian scribes date back to the Old Kingdom (*c*.2600 BC). They belonged to a body of officials who served the Kingdom, as did their Assyrian and Babylonian counterparts. Even more professional were the Chinese functionaries employed in the imperial court. These officials – better known as 'mandarins' – were selected by rigorous examinations, paraded through the villages with servants carrying their desks and proudly displaying their rank in the shape and color of their hat tassels. The term 'mandarin' was later used pejoratively to indicate the aloofness of civil servants, the official jargon, and the sheltered life of their long careers.

Broadly speaking, the history of public administration testifies that there has always been a need to link state (or ruler) goals, with the official expertise of a bureaucracy that tends to be centralized. These bureaucratic entities were engaged in three main types of activities: technical services such as land registration or water allocation; social and political regulation such as administrating justice, collecting taxes, or supervising weights and measures; and above all – managing war-related affairs (Finer, 1997: vol. 1, pp. 59–72).

The European patterns of the civil service have emerged gradually from the Greek and especially the Roman law and administrative traditions of various public functions such as public construction, food supply regulation, and population census. They were later influenced by the medieval feudal system of financial and judicial administration. Yet, the most strenuous collective effort has always been related to mobilizing money, soldiers, and equipment for the military. Accordingly, throughout the history of most countries, public

and private organizational practices have been influenced directly by the most readily available example – the military model. This model was further developed to encompass the colonial expansion of some European countries, which required new organizational expertise, both in content and in scope. The influence of the military is most readily seen through such administrative concepts as 'chain of command,' or 'line and staff,' so much so that attempts to 'debureaucratize' the civil service (e.g., creating less hierarchical departments) are essentially an attempt to break away from the dominance of the military bureaucratic model.

The Modern Civil Service

The emergence of the modern civil service is connected to the crystallization of the European-style state, first in France and Prussia and later in all the 200 or so states that populated the globe in the early twenty-first century. As an institution, the civil service dates back to the middle seventeenth century with the inauguration of competence entrance examinations in Prussia under Friedrich Wilhelm I, analogous to the old Chinese practice. Equally important, the German Cameralists were the first modern scholars–practitioners to study public administration and to offer a set of principles for the 'management of the state' (Gross, 1964: vol. I, p. 108). The next stages in the development of the civil service were diffused, but a few milestones can be presented, all of them related to the attempt to create an institutional instrument with acquired experience in running state affairs. The dissimilar features should also be noted as each civil service is also a product of its particular environment, and the human composition of each of them reflects recurring attempts of social groups to enter the ruling elites of their respective states.

The Napoleonic Reforms in the early nineteenth century converted the previous French royal service into a State public service. France, and before that Prussia, created the continental model of a central, professional, tenured, and in-house trained civil servant. More than in other countries, continental civil servants embody the state, and the continuity of state affairs, and operate within a specific legal framework of administrative law (Crozier, 1964; Suleiman, 1974).

The Northcote–Trevelyan report (1854) in Britain introduced competitive examinations into the civil service and uniform methods of recruitment and promotion across departments. It eventually succeeded in eliminating patronage. As the senior administrative class became a professional life career it attracted educated professionals who were given the task of shaping public policy and advising politically elected ministers. Below senior civil servants were the executive and clerical classes, entrusted respectively with managerial and routine responsibilities. The UK was the first to establish a civil service commission to oversee the entire operations of the civil service. Politically neutral and very secretive, the British senior home civil service acquired a reputation of integrity and impartiality, and of being rather conservative guardians of crown affairs, as distinct from the governments of the day.

The Pendelton Act (1883) in the United States marked the beginning of federal civil service reform, aimed at abolishing the previous 'spoils system' in the government. Patronage in the federal government was closely related to electoral turnovers in the Presidency and Congress. Unlike the UK, the American system has never achieved the same degree of uniformity, political neutrality, or continuity. However, the American civil service has been much more open, with recruitment to the senior positions less dependent on social class and on elite education systems. Consequently, the U.S. civil service has never had the aura of 'officialism' as in Europe, and has not acquired the prestige and the consequent status of being a permanent agent of the federal state.

Nondemocratic Regimes

In nondemocratic regimes, the position of the civil service institution is related directly to the scope of the state's monopoly of the different spheres of life. The stronger the state, the more dominant is the public bureaucracy – operating sometimes from the ruler's palace, the military barracks, or the party's headquarters. In such regimes, the civil service hardly exists as a differentiated professional institution. In the former Soviet Union, for example, the lines between state and party bureaucracies, and indeed between political and administrative decisions, were (and are still today in China) practically nonexistent. In this respect, the most troubling phenomenon appeared with the total submission of the highly developed German civil service (including the military and the judicial) to Nazi leaders. This raises the question: Can there be safeguards against turning professional competence – and loyalty – into a sharp tool in the hands of evil political masters?

New States

In many new states, the civil service is a mixture of colonial heritage and unique local features. In India, and in some other former British colonies, the civil service is a strong institution, and it helps to keep the country going, despite recurring crises and accusations that it impedes development. In other new countries, particularly where the military took over, the civil service hardly functions. It cannot maintain law and order, let alone carry the task of providing social services. The weaker the state, the more helpless is the civil service institution; the weaker the civil service, the lesser its ability to maintain stability and introduce positive changes. However, nondemocratic states may have very strong military or even civilian bureaucracies. When state-building efforts are proposed, the importance of the civil service institution is duly stressed (Fukuyama, 2004). Accordingly, the popular revolutions in the Arab world that started in 2011 used the slogan of 'democratizing' the state civil service.

The Rational Model

Max Weber (1864–1920) delineated three 'ideal-types' of legitimate authority – the legal-rational, the traditional, and the charismatic, and suggested that the first one requires the existence of a 'rational' administrative staff. Strongly influenced by the Prussian example, Weber drew a list of the characteristics of a modern bureaucracy and the conditions that contributed to its emergence and growth, particularly in capitalist market

economies (Weber, 1947). His ideas reflected, and to some extent strengthened, the heavy reliance – both in continental Europe and in the United States – of civil service institutions upon administrative law: legal codes, rules, regulations, and precedents. The notable exception was the UK that (unlike Canada, Australia, and its other former dominions) did not have a civil service act of Parliament until the Constitutional Reform and Governance Act of 2010.

The rational ('Weberian') model of the civil service as a permanent institution – influenced by the military model – also includes the following common features, which are assumed to exist in the public bureaucracies of the developed states: the centralization of authority; formal modes of operation; a central commission or agency in charge of civil service affairs; established procedures for recruitment, tenure, promotion, compensation, job evaluation, discipline, and the right to associate and strike; and arrangements for securing political neutrality. In addition, civil servants must adhere to a special service code of conduct which specifies their obligations, and constitutes the ethos (or perhaps the myth) of impersonality, neutrality, and guardianship of state secrets.

The important point about the rational model of the civil service is that there is a connection between the development of the modern state and this new form of bureaucratic organization. Indeed, in the twentieth century the civil service and the entire public sector expanded rapidly in response to growing roles of the state, particularly with the growth of the welfare state. Governments and their civil service apparatus have been given the task of providing more services and of finding answers to new problems such as environmental degradation. However, at the same time, the 'administrative' or 'bureaucratic' state has also come under attack, in terms of the size, structure, and functions of the civil service. New post-Weberian questions have been floated: to whom should the civil service be responsive and accountable: to the state, the law, the government of the day, the multicultured conglomeration of sectors, groups, and citizens, or perhaps to the individual customers of its services? These questions paved the way for new democratic demands: citizen involvement and participation in policy making, in addition to the indirect supervision of the civil service through its political masters.

What Do Civil Servants Do?

Civil servants are in charge of a rich menu of government activities ranging from artificially 'seeding clouds' in the sky to induce rainfall, to operating schools, or administrating programs for the increasing number of aged people. In between, civil servants, as in ancient times, continue to collect taxes and perform state functions that cannot be trusted to or executed by social (voluntary) or private market institutions. These various activities can be grouped under the following headings: shaping and implementing public policy decisions; providing services to individuals, groups, and organizations; and administrating regulatory functions in areas such as aviation, drugs, and election financing.

The main structural entities for carrying out these activities could be divided roughly into: (1) the regular civil service departments and agencies – responsible for the generic governmental functions; (2) the special statutory agencies, authorities and commissions (e.g., the U.S. Securities and Exchange Commission) responsible for specific tasks removed from the regular civil service, increasingly including regulatory tasks; and (3) government corporations entrusted with running mainly utilities and other commercial enterprises regarded as natural monopolies (e.g., electricity companies; regional development projects), or in some other way related to merit public goods and national interests (e.g., national forests, postal services, public broadcasting). The combinations of the various types of activities and the different structures reflect the myriad and ever-changing scope of civil service responsibilities, including 'joined-up government' or 'collaborative governance' (Bogdanor, 2005; Donahue and Zeckhauser, 2011) – aimed at bringing together different government agencies and private and voluntary bodies, thus blurring the previous boundaries of the civil service.

It is impossible to prescribe the right number of civil servants per capita, given the differences in their functions, and in the number of intrastate governmental levels in different states. In economically developed states, the tendency is to cut down the scope of civil service activities (and consequently its size as well) through privatization, outsourcing, and delegation of responsibilities to nonprofit civil society organizations. In new states, the pressure still exists on the civil service to do much more for their hard-pressed societies.

Studying the Civil Service

Woodrow Wilson (1887) was among the pioneers who attempted to create 'a practical science of administration,' aimed at improving not only the personnel, but also the organization and methods of government offices. He saw the field of administration as a field of business that should be outside the sphere of politics. Hence his famous dictum: separate policy making from administrative execution. However, there were other scholarly currents as well. From the 'scientific management' movement in the United States (*c.*1900s) came the notion of 'efficiency,' aimed at increasing workers' productivity through detailed time and motion studies, standardization of tools, and careful attention to training. From the 'human relations' school (*c.*1930s) came the behavioral message that in all organizations, individual and group motivations are critical factors. A little later, and more directly applied to public administration, attempts were made to develop prescriptive principles. For instance, establish one top executive; fit people to organizational structures; ensure unity of command; use specialized staff; maintain homogeneity in organizational subdivisions; delegate authority; match responsibility with authority; and limit span of control (Gulick and Urwick, 1937).

Theoretically, these 'principles' were not only culturally restricted, but inherently anecdotal and Herbert Simon (1946) regarded them as no more than 'proverbs of administration.' Simon's concept of 'bounded rationality' that governs the life of all organizations, was a step away from prescriptions toward observations, and from practical advice on how to run organizations to laying the foundation of public administration theory and of a comparative perspective. First came the formal studies of the civil service as an institution within the executive

branch, or in the context of administrative law. Later, mainly because of the impact of studies in political science, the context as well as the horizon were expanded, away from the previous formalism. For example, power, group theory, and communication were introduced into the vocabulary of public administration research.

The related area of public policy has recently emerged with new emphasis on economic models and game theory, as well as on the redefinition of values, public goods, and the role of politics in decision-making (Majone, 1989). New foci were introduced such as implementation, social regulation, and comparative policy analysis in areas such as welfare, health, and environment (Goodin and Klingemann, 1996). More recently, the nature of policy making has been studied empirically with emphasis on policy processes and transformations (Jones and Thomas, 2013).

The most challenging and inadequately researched new area has remained the role of the civil service institution in democracies. This is a practical issue as well: how to reform the civil service within a new democratic framework in the era of state weakening (Silberman, 1993).

A New Version of the Civil Service?

In the 1980s, a number of Organization for Economic Cooperation and Development countries adapted a 'New Public Management' (NPM) doctrine that was founded on principles of organizational best practices and public accountability (Hood et al., 1999). In NPM reforms were introduced, a new post-public bureaucracy model was assumed to emerge with entirely new roles for the civil service (Peters and Wright, 1996). A key assumption was that the NPM reforms would lead to a diminished public bureaucracy, and perhaps even a nonexistent civil service (Olsen, 2008).

The institute of the state continues to change rapidly in the twenty-first century, and if there is going to be a 'skeleton state,' there will be a skeleton civil service as well. This process has been gradually occurring both because of internal changes such as the weakening of public trust in political institutions, and under the impact of globalization. In recent years there are states still struggling to build a British-type civil service (which does not exist in the UK anymore); other states in which few changes have taken place in their public bureaucracies; and economically rich states in which the traditional role of the civil service is visibly contracting. There are also new suprastate bureaucracies, not only in international organizations such as the United Nations or the European Union, but also in interstate agencies and in joint public management of regional projects. These developments have shattered many of the old features of the classical Weberian-type civil service.

Examples:

1. Civil service monopoly on official information is no longer feasible and government secrecy has yielded to freedom of information acts enacted in almost all democratic states (Galnoor, 1989). State secrets too are no longer immune, as exemplified by the disclosure of numerous highly classified U.S. government documents by E. Snowden in 2013 (Harding, 2014).
2. With modern information technology and social networks, civil servants' discretion in shaping public policy (and perhaps anonymity too) has been gradually disappearing.
3. The previous civil service – interest groups network, has been replaced by a much more intricate and uncontrollable system of organization in the mushrooming 'third sector' (nongovernmental, nonprofit) of public groups, NGOs, and philanthropic funds.
4. The civil service is under great pressure to be more 'representative' in its membership, or at least to assist in achieving equal opportunity through 'affirmative action' and other 'open government' measures.
5. Direct accountability of the civil service to the public is demolishing the last walls of insulation. One example is the spread of the Swedish Ombudsman institution. Another is the authority given to special investigation commissions to probe the decision-making discretion of public officials.

These developments were followed by changes in the traditional features of the civil service. For example, in many states the civil service is no longer a life-long career and new opportunities for entrance to (and exit from) senior positions have been introduced. The emphasis on management skills has downgraded the policy-advice roles of civil servants. The results-oriented business approach has diverted attention to the quality of service aspect, including the idea that civil servants should be rewarded according to their standing in customers' satisfaction surveys.

The increased prominence of a business approach in the civil service has influenced the relationship between the civil service and the public to whom it is accountable (Vigoda, 2002). Even as the civil service increasingly relates to citizens as clients, recent channels have developed for including citizen input in policy making and decision making, whether through networks, nongovernmental organizations, or through direct democracy initiatives (Fung, 2006). A related development is the slow emergence of 'e-Government' as a tool for public management and innovation. The original use of Information and Computing Technologies (ICT) was for increased efficiency of internal civil service functioning, but they became used more frequently to improve the quality of service provision. The most promising ICT use is to support citizen involvement and participation in democratic policy making. Indeed, there is evidence that these technologies facilitate innovation in the public sector (Tolbert et al., 2008). Yet, it remains to be seen whether these tools will meaningfully change the previous one-sided relationship between civil servants and the public (Hood, 2006).

The Impact of Privatization on the Civil Service

As part of the process of 'reshaping the state,' the size, structure, and functions of the civil service are in transition, with independent public and private entities and agencies performing what used to be civil service tasks. Other functions have been 'privatized,' 'marketed,' or 'outsourced': running prisons, computer services, or even recruitment to the civil service itself. Privatization in its narrow, technical sense is the transfer of assets, services, and goods from the ownership and/or

management and/or financing by state and substate governmental organizations to market organizations, or to organizations of the nonprofit sector. From a broader perspective, privatization is a new ideological definition of state responsibility aimed at shifting the boundaries between public and private (or market) allocation. The premise behind this approach is that goods and services are produced more efficiently and with less opportunity for corruption by private organizations. Based on these assumptions, a wide range of public services has been privatized since the 1980s in many countries, thus reducing the role and responsibility of the state, particularly the intervention of the executive branch, in economic and social affairs (Galnoor, 2011: pp. 150–158).

Privatization and outsourcing have led to increasing ambiguity about the boundaries of responsibility between the private and public sectors, as well as to some attempts at cooperation between the two. Another outcome has been the growth of a powerful third sector that has appropriated many areas traditionally considered the responsibility of the state, either willingly or out of necessity. The results of these processes in many countries have been that government ministries and local authorities virtually ceased functioning in certain areas, while private and voluntary organizations operate in their stead. The broader context is society's transitions from one based on a civil orientation that places heavy obligations on the state to one based on a consumer orientation that perceives its citizens as clients. This has resulted in increased regulation, but in many cases, privatization did not produce real competition or better, cheaper services. The ability of the state to regulate lagged behind the increased power and expertise of the bodies in charge of privatized and contracted-out goods and services. In addition, the assumption that privatization will reduce corruption has not been at all substantiated. Areas of privatization can be categorized as follows:

1. The Privatization of Public Goods: the government's exit from activities such as road building, mining, and communications. The assumption is that privatization will lead to increased competition and thus greater efficiency and improved services. Examples are the sale of government-owned corporations, such as oil refineries, ports, roads, and railways. Privatizations such as these evoke questions about the transparency of the process, the appropriate compensation for public assets transferred, the danger of creating private monopolies accountable to no one, the balance between beneficiaries and losers, the violation of labor rights and agreements, and the effectiveness of postprivatization regulation.
2. The Privatization of Public Services: usually contracting out health services, education and welfare previously delivered by the state or local authorities. This type of privatization comes about because of a gradual reduction in services, cutbacks in funding, creating gaps often filled by private providers, for example, cutbacks in law enforcement have led well-to-do homeowners to install security cameras and employ private security firms.
3. The Privatization of Operations: appears under different names such as outsourcing, partnerships, franchises, subcontracting, and voucher distribution. This type of privatization may be full or partial, involving either the acquisition of private services by the government or the transfer of operations to the private or voluntary sector. The responsibility remains in the hands of the state, sometimes effectively regulating the delivery of the product or the services, and sometimes helplessly watching its deterioration. These arrangements, prevalent in the business sector, are often motivated by a desire to scale down the public sector or increase so-called 'flexibility' in management and employment. Privatization of operations can lead, however, to the violation of workers' rights, as may occur when work is outsourced to private service contractors. If outsourcing involves the transfer of policy making out of the civil service, one must consider the potential injury to the public and particularly to helpless people.

Thus, privatization has been a profound reform in the structure and functions of the civil service, raising many questions about the role of the state and its regulation performance.

The Civil Service and Regulation

Regulation refers to laws and rules that are binding on the conduct of organizations and individuals, and the regulator is responsible for formulating and enforcing these rules. This definition refers primarily to the oversight of business organizations by the state. A broader definition emphasizes the social–political role: focused and continuing supervision by a public body over socially significant activities (Selznick, 1985). In this definition, regulation is more than law enforcement and its aim is to attain social goals, including the proper functioning of the economy.

The civil service deals with regulation through legislation, rules, and other regulatory mechanisms. Regulation laws are concerned with licensing professionals in sensitive occupations (such as accounting), safeguarding the individual's property rights (patents), ensuring the functioning of the financial market (securities), preventing epidemics (food), and supervising the use of a collective good such as space (satellites). Other regulations seek to cope with 'market failures,' such as the absence of competition, the marketing of dangerous products, the lack of transparency to consumers, and environmental pollution. The list could also include common social motivations such as regulating the public labor force by the use of affirmative action, supervising the use of drugs, and control over the use of public resources such as the coastline.

Opponents of regulation associate it with bureaucratic red tape, and point out the inflexibility, convoluted procedures, excessive control and demand for permits, and its high cost. Proponents of regulation point out that we, as citizens, want the state to oversee greater regulation in many key areas, such as protection from building violations, prevention of safety and traffic hazards, environmental preservation, and so forth. Others believe that a 'regulatory state' is about to replace the 'dirigiste state' that preceded it and regulation will thus supersede state ownership of organizations; rather than government intervening in planning and implementation, it will focus on oversight and control (Majone, 1994; Levi-Faur, 2011).

Blurred Boundaries of the Civil Service and Continued Relevance

As the enthusiasm for New Public Management reforms faded in the twenty-first century, the three main tasks of public servants mentioned above (i.e., shaping and implementing policy decisions; providing services; and regulating public functions) are still within the responsibility of the public bureaucracy. Even as these tasks are increasingly contracted out, the expertise of the civil servants who contract for and regulate these tasks is still required. The most important change that has occurred, therefore, is the blurring of the old boundaries between the public and private sectors, and between politics and administration.

Merriam (1944) pointed out the blurred boundary long ago: the civil service has constituencies, and in many countries, corporations exert a great deal of influence on public policy. However, with increased regulation, the private sector became even more involved, and hence the phenomenon of excessive clientelism (Nadel and Rourke, 1975). Increased globalization and the diffusion of public management practices between countries have also blurred the autonomous domain of the civil service (Matthiasan, 2005).

As for the politics–administration dichotomy, for many years it disappeared from public administration textbooks. Everybody knew that civil servants exercise state power both formally (law application) and informally (policy shaping). However, starting in the 1980s the distinction returned as part of NPM. The textbooks dealing with the civil service are called 'introduction to public sector management,' and the civil service is conceived to be market-oriented, customer-driven, deregulated and decentralized. Thus, the old Wilsonian dichotomy has returned through the back door: an institutional separation within the civil service between the 'departments' in charge of policy and the 'performance-based organizations' or 'executive agencies' responsible for delivering services to customers.

What is therefore the outlook for the institution of the civil service? New democracies have learned the hard way that state-building means institution-building and that a key institution is an old-fashioned autonomous civil service. In advanced countries, crippling the civil service resulted in diminished state capacity to deal with natural disasters, or with financial corruption in the private sector. Moreover, it seems to curtail the collective ability to invest in innovation and there are calls for reinstating the 'entrepreneurial state' (Mazzucato, 2013). If this line of thinking will prevail, the continued relevance of the civil service will be assured.

Civil Society and the Public Sphere: History of the Concept

Abstract

The concept of the public sphere refers to the capacity of the members of civil society to coordinate their common affairs through collective discourse which transcends the private interests of each. The concept is associated especially with the theories of Hannah Arendt and Jurgen Habermas. Current work focuses especially on the relationship between rational-critical communication and other dimensions of culture-formation and expressive communication; on issues of diversity in participation, topics, and communicative styles; and on the relationship of the public sphere to state-centered politics and/or the transcendence of the state in an international public sphere.

The closely related concepts of civil society and public sphere developed in the early modern era to refer to capacities for social self-organization and influence over the state. Civil society usually refers to the institutions and relationships that organize social life at a level between the state and the family. Public sphere is one of several linked terms (including 'public space,' simply 'public,' and the German *Öffentlichkeit*, or publicness) that denote an institutional setting distinguished by openness of communication and a focus on the public good rather than simply compromises among private goods. Located in civil society, communication in the public sphere may address the state or may seek to influence civil society and even private life directly. Key questions concern the extent to which it will be guided by critical reason, and how boundaries between public and private are mediated.

Civil Society and Self-Organization

The distinction of 'civil society' from the state took its modern form in the seventeenth and eighteenth centuries. Prior to this separation, political and social realms were seldom clearly distinguished. When they were, the social was exemplified by the family and often subordinated as the realm of necessity or mere reproduction to the broader public character and possibilities for active creation that lay in the state. The Greek conception of the *polis*, for example, usually referred to both, but when a distinction was made, it clearly favored the state.

Roman law contributed the idea of *civitas* and a stronger sense of relations among persons that were neither narrowly familial nor specifically about constituting the political society through the state. Medieval political and legal theory developed this theme, especially in relation to the freedoms claimed by medieval cities but also in relation to the Church. Some strands juxtaposed the notion of legitimacy ascending from 'the people' to the eventually dominant idea of divine right of kings, with its notion of legitimacy descending from God. Also influential was the distinction of civil from criminal law (in which the former governs relations formed voluntarily among individuals and the latter the claims of the whole society against malefactors). Nonetheless, it was only in the course of early modern reflection on the sources of social order that civil society came to be seen as a distinct sphere.

A crucial step in this process was the 'affirmation of ordinary life' (Taylor, 1989). Whereas the Greek philosophers had treated the private realm – including economic activity – as clearly inferior to the public realm associated with affairs of state, many moderns placed a new positive value on family and economic pursuits. They argued that both privacy and civil society needed to be defended against encroachments by the state. In this context, it was also possible to conceive of a public sphere that was not coterminous with the state but rather located in civil society and based on its voluntary relations. In this communicative space citizens could address each other openly, and in ways that both established common notions of the public good and influenced the state.

Social contract and natural law theories – especially as joined in the work of John Locke – contributed to this shift by suggesting ways in which the creation of society conceptually preceded the creation of government. From this it was only a short step to say that the legitimacy of government depended on its serving the needs of civil society (or of 'the people'). Thomas Paine and other advocates of freedom from unjust rule advanced an image of the freedoms of Englishmen which was influential not only in England and America, but in France, notably in Montesqueiu's account of the 'spirit' of laws which combined an appreciation of English division of powers with an older tradition of republican (and aristocratic) virtue. From Rousseau through Tocqueville, Comte, and Durkheim, this French tradition developed an ever-stronger account of the autonomy of the social (resisting not only the claims of the state but the Cartesian postulate of the primacy of the individual subject).

A crucial innovation was to understand society as at least potentially self-organizing rather than organized only by rulers. If there was a single pivotal intellectual source for this, it lay with the Scottish moralists. In Adam Smith's (1776) notion of the invisible hand, the market exemplified this self-organizing capacity but did not exhaust it. In his *Essay on the History of Civil Society* (1767), Adam Ferguson presented human history as a series of social transformations leading to modern society.

This prompted Hegel (1821) to treat civil society as a field in which the universal and particular contended; their reconciliation depended on the state. The idea of civil society also shaped classical political economy and ideas of social evolution, and informed Marx's account of the stages of historical development as combinations of productive capacity and (conflict-ridden) social relations. Marx also challenged the notion that markets were neutrally self-organizing, emphasizing the role of historical accumulations of power.

Though the actual analyses differed, what had been established was the notion of society as a distinct object of analysis, not reducible to either state or individual. People formed society impersonally as actors in markets, more personally as parties to contracts. The idea of civil society hearkened back to the sort of social life that emerged among the free citizens of medieval cities because this was largely self-regulated – as distinct from direct rule by ecclesiastical or military authorities. It also suggested 'civility' in interpersonal relations. This meant not just good manners, but a normative order facilitating amicable or at least reliable and nonthreatening relationships among strangers and in general all those who were not bound together by deep private relations like kinship. Equally important, the idea of civil society included – in some versions – the notion that communication among members might be the basis for self-conscious decisions about how to pursue the common good. This notion is basic to the modern idea of public sphere.

The Idea of a Public Sphere

Rousseau (1762) famously sought to understand how social unity could result from free will rather than external constraint. This depended, he argued, on transcending the particular wills of many people with a general will that was universal. Kant admired Rousseau's pursuit of unity in freedom as distinct from mere social instinct (as in Aristotle's notion of a political animal) or imposition of divine authority. He relied implicitly on the idea of a collective conversation through which individual citizens reach common understandings. Likewise the development of representative institutions in eighteenth century England informed and anchored a public discourse directed at bringing the will and wisdom of citizens to bear on affairs of state. Finally, the idea of the people as acting subject came to the fore in the American and French revolutions. The idea of a public sphere anchored democratic and republican thought in the capacity of citizens in civil society to achieve unity and freedom through their discourse with each other.

Kant, like many eighteenth-century philosophers, lacked a strong notion of the social. This Hegel (1821) supplied, rejecting social contract theory because even in Rousseau's notion of a general will it suggested that the union achieved in the state depended not on its own absolute universality but on a development out of individual wills. Nationalism also shaped ideas of society and political community in holistic ways well matched to unitary states (Calhoun, 1999). Marx's (1843/1975, 1927/1975) critique of politics based on bourgeois individual rights further challenged the adequacy of civil society as a realm of freedom and unity. Where Hegel thought that the state in itself might overcome the tension between necessity and freedom and the clash of particular wills, Marx held that only a transformation of material conditions including the abolition of private property could make this possible. As a result, theories stressing stronger ideas of the social were apt to offer weaker notions of public life. The Marxist tradition denigrated 'mere democracy' as an inadequate means of achieving either freedom or unity.

The ideas of public sphere and civil society developed primarily in liberal theory. These were not always seen in the manner of Hegel as merely 'educative' on the way to a more perfect latter unity. Nor was political unity necessarily left to the workings of an invisible hand or other unchosen system, but freedom was treated commonly as a matter of individual rather than collective action. This accompanied the rise of relatively asocial understandings of the market (Polanyi, 1944). In addition, the emerging notion of the public sphere was not clearly distinct from other usages of 'public.' State activity, for example, was sometimes described as public without regard to its relationship to democracy or its openness to the gaze or participation of citizens. This usage survives in reference to state-owned firms as 'public' regardless of the kind of state or the specifics of their operation.

More important was the overlapping concept of 'public opinion' (*see* Public Opinion: Social Attitudes). The dominant eighteenth-century usage emphasized open expression and debate, contrasting free public opinion to absolutist repression. At the same time, it generally treated public opinion as a consensus formed on the basis of reasoned judgment. 'Opinion' was something less than knowledge, but especially where it had been tested in public discourse, it was not simply sentiment and it gained truth-value from reflexive examination. Various euphemisms like 'informed opinion' and 'responsible opinion,' however, reflected both a bias in favor of the opinions of elites and an anxiety about the possibly disruptive opinions of the masses. During the nineteenth century, this anxiety came increasingly to the fore. Tocqueville (1840/1844/1961) and Mill (1859), thus, both contrasted public opinion to reasoned knowledge; Mill especially worried about 'collective mediocrity' in which the opinion of debased masses would triumph over scientific reason. While advocates of the public sphere saw rational-critical discourse producing unity, critics saw mass opinion reflecting psychosocial pressures for conformity. Implicitly, they associated reason with individuals rather than any collective process. The distinction between 'public' and 'crowd' or 'mass' was lost in such views (Splichal, 2000). Early positivist research into public opinion approached it as explicable on the basis of social psychology rather than as a species of reasoned argument. Toennies (1922/2000) sought a way to discern when each approach ought to apply.

Conversely, in the late nineteenth and twentieth centuries, a new field of public opinion research developed that approached public opinion as an aggregation of individual opinions. The shift was based largely on the development of empirical polling methods. It brought a renewal of attention to differences within public opinion, and thus to the distinction between public and crowd (Blumer, 1948; Key, 1961). It also focused attention on patterns of communication among members of the public rather than the more generalized notions of imitation or emotional contagion. New media – first

newspapers, and then broadcast – figured prominently in efforts to understand public communication. While Lippman (1960) and a variety of social psychologists worried that the new media would produce the descent to a lowest common denominator of public opinion that liberals had long feared, Dewey (1927) and other pragmatists defended the capacity for reason in large-scale communication. In this, they hearkened back to the eighteenth-century hopes of Kant and Rousseau.

Even before the apotheosis of the opinion poll, Cooley (1909) had argued emphatically that public opinion ought to be conceived as 'no mere aggregate of individual opinions, but a genuine social product, a result of communication and reciprocal influence.' A key question was whether this communication and reciprocal influence amounted to the exercise of reason. Peirce (1878/1992) had argued that among scientists the formation of consensus on the basis of openness and debate was the best guarantee of truth. Could this view be extended into less specialized domains of public discourse? This has been an enduring focus for Jurgen Habermas, the most influential theorist of the public sphere.

Habermas

In the context of some cynicism about democratic institutions, Habermas (1962/1991) set out to show the unrealized potential of the public sphere as a category of bourgeois society. He challenged most directly the tendencies in Marxism and critical theory to belittle democratic institutions – and also the collapsing of public into state characteristic not only of Hegel but of actually existing socialism. Habermas celebrated the emancipatory potential of a collective discourse about the nature of the public good and the directions of state action. This could be free insofar as it was rational – based on the success of argument and critique rather than the force of either status or coercion – and could achieve unity by disregarding particular interests – like particular statuses – in favor of the general good. The best version of the public sphere was based on 'a kind of social intercourse that, far from presupposing the equality of status, disregarded status altogether.' It worked by a 'mutual willingness to accept the given roles and simultaneously to suspend their reality' (Habermas, 1962/1991, p. 131).

The basic question guiding Habermas' exploration of the public sphere was: to what extent can the wills or opinions guiding political action be formed on the basis of rational-critical discourse? This is a salient issue primarily where economic and other differences give actors discordant identities and conflicting interests. For the most part, Habermas took it as given that the crucial differences among actors were those of class and largely political-economic status; in any case, he treated them as rooted in private life and brought from there to the public. He focused on how the nature, organization, and opportunities for discourse on politically significant topics might be structured so that class and status inequalities were not an insuperable barrier to political participation. The first issue, of course, was access to the discourse. This was not so simple as the mere willingness to listen to another's speech, but also involved matters like the distribution of the sorts of education that empowered speakers to present recognizably 'good' arguments. Beyond this, there was the importance of an ideological commitment to setting aside status differences in the temporary egalitarianism of an intellectual argument.

The public sphere joined civil society to the state by focusing on a notion of public good as distinct from private interest. It was however clearly rooted in civil society and indeed in the distinctive kind of privacy it allowed and valued.

The bourgeois public sphere may be conceived above all as the sphere of private people coming together as a public; they soon claimed the public sphere regulated from above against the public authorities themselves, to engage them in a debate over the general rules governing relations in the basically privatized but publicly relevant sphere of commodity exchange and social labor. The medium of this political confrontation was peculiar and without historical precedent: people's public use of their reason (Habermas, 1962/1991, p. 27).

This public use of reason depended on civil society. Businesses from newspapers to coffee shops, for example, provided settings for public debate. Social institutions (like private property) empowered individuals to participate independently in the public sphere; forms of private life (notably that of the family) prepared individuals to act as autonomous, rational-critical subjects in the public sphere. But the eighteenth-century public sphere was also distinguished by its normative emphases on openness and rational political discourse. Habermas' concern focused on the way later social change brought these two dimensions into conflict with each other.

The idea of publicness as openness underwrote a progressive expansion of access to the public sphere. Property and other qualifications were eliminated and more and more people participated. The result was a decline in the quality of rational-critical discourse. As Habermas later summed up:

> Kant still counted on the transparency of a surveyable public sphere shaped by literary means and open to arguments and which is sustained by a public composed of a relatively small stratum of educated citizens. He could not foresee the structural transformation of this bourgeois public sphere into a semantically degenerated public sphere dominated by the electronic mass media and pervaded by images and virtual realities.
>
> (Habermas, 1998, p. 176)

While Habermas' account of the continuing value of the category of public sphere evoked by the eighteenth-century ideal set him apart from Horkheimer and Adorno (1944/1972) and their pessimistic turn in critical theory, he largely incorporated their critique of 'mass society' as 'administered society' into his survey of twentieth-century developments and with it many of the fears of nineteenth-century liberals. He held that the public sphere was transformed not only by simple increase of numbers but by the success of various new powers at re-establishing in new form the power to 'manage' public opinion or steer it from above. Public relations agents and public opinion polls replaced rational-critical debate; electronic media allowed openness but not the give and take conversation of the eighteenth-century coffee houses. At the same time, rising corporate power and state penetration of civil society undermined the distinction of public and private, producing a 'refeudalization' of society.

Arendt

Hannah Arendt also focused on the problem of collapsing distinctions between public and private. Arendt emphasized the capacity of action in public to create the world that citizens share in common. The term 'public,' she wrote, 'signifies two closely interrelated but not altogether identical phenomena: It means, first, that everything that appears in public can be seen and heard by everybody and has the widest possible publicity. … Second, the term "public" signifies the world itself, in so far as it is common to all of us and distinguished from our privately owned place in it' (Arendt, 1958, pp. 50, 52). Public action, moreover, is the crucial terrain of the humanly created as distinct from the natural world, of appearance and memory, and of talk and recognition. Such action both requires and helps to constitute public spaces – spaces held in common among people within which they may present themselves in speech and recognize others. Public action is thus a realm of freedom from the necessity – notably of material reproduction – that dominates private life.

Arendt's usual term, 'public space,' leaves the 'shape' of public life more open than the phrase public sphere. Public action can create institutions, as in the founding of the American Republic, but as action it is unpredictable. Its publicness comes from its performance in a space between people, a space of appearances, but it is in the nature of public action to be always forming and reforming that space and arguably the people themselves. This conceptualization offers clear advantages for thinking about the place of plurality in the public sphere. As Arendt wrote of America, 'since the country is too big for all of us to come together and determine our fate, we need a number of public spaces within it' (1972, p. 232).

Arendt saw this plurality threatened not just by mass conformity but by the reduction of public concerns to material matters. A focus on sex as much as on the economy threatens the public–private distinction. It not only intrudes on intimacy and private life but impoverishes public discourse. Arendt (1951) saw this problem as basic to totalitarianism, which could allow citizens neither privacy nor free public discourse. Totalitarianism is distinguished from mere tyranny by the fact that it works directly on private life as well as limiting public life. This is not just a matter of contrasting intentions, but of distinctively modern capacity. Modern sociological conditions offer rulers the possibility to reach deeply into the family in particular and personal life in general, to engineer human life in ways never before imagined.

This potential for collapsing the public and private realms is linked to Arendt's unusually negative view of civil society. 'Society,' she writes, is 'that curious and somewhat hybrid realm which the modern age interjected between the older and more genuine realms of the public or political on one side and the private on the other' (1990, p. 122). Civil society is first and foremost a realm of freedom *from* politics. But public freedom is freedom *in* politics. This calls for action that creates new forms of life, rather than merely attempting to advance interests or accommodate to existing conditions. This distinguishes Arendt's view, and republicanism generally, from much liberal thought: 'Thus it has become almost axiomatic even in political theory to understand by political freedom not a political phenomenon, but on the contrary, the more or less free range of nonpolitical activities which a given body politic will permit and guarantee to those who constitute it' (1990, p. 30).

The founding of the United States was a favorite example of such action for Arendt. The American Founders imagined and created a new kind of society, a new set of institutions. This relied on citizens' public commitments to each other rather than assumptions about human nature or mere external application of law. The Founders 'knew that whatever men might be in their singularity, they could bind themselves into a community which, even though it was composed of "sinners," need not necessarily reflect this "sinful" side of human nature' (1990, p. 174). Arendt's vision of public life as central to a moral community shares much with a republican tradition that deplores the modern decline of the public sphere – generally associated with the rise of particular interests at the expense of concern for the general good, the deterioration of rational public discourse about public affairs, or outright disengagement of citizens from politics (*see* Public Sphere: Nineteenth- and Twentieth-Century History). Republican accounts of the public sphere place a strong emphasis on the moral obligations of the good citizen; recent scholarship has often questioned whether citizens lived up to significantly higher standards in earlier eras (Schudson, 1998).

Differentiation in the Public Sphere and Civil Society

Habermas' account of the public sphere has been enduringly influential (see Calhoun, 1992). Its delayed translation into English in 1989 ironically contributed to an invigorating new reading shaped by both the fall of communism and widespread projects of privatization in the West. Critics within communist societies had revived the notion of civil society (as distinct from simply 'society') in order to speak of the realm outside state control and its relative absence in communist societies. Likewise, transitions away from right-wing dictatorships were often treated in terms of a 'return of civil society' (Perez-Diaz, 1993). In the US, the idea of civil society was linked not only to democracy but to reliance on voluntary organizations and philanthropy (Powell and Clemens, 1998; Putnam, 2000).

What civil society signifies in contemporary political analysis is the organization of social life on the basis of interpersonal relationships, group formation, and systems of exchange linking people beyond the range of intimate family relations and without reliance on direction by the government. As a number of scholars of Africa have noted, it incorporates an unfortunate understanding of family privacy that underestimates the positive and supraprivate social roles that African kin organizations can play (see essays in Harbeson et al., 1994). Even more basically, references to civil society often fail to distinguish adequately between systemic capitalist economic organization and much more voluntary creation of social organization through the formation of civic associations, interest groups, and the like – a distinction Habermas has sought to stress. This has sometimes been a source of confusion in use of the public sphere concept to analyze distinctive institutional developments in diverse political and cultural settings (Calhoun, 1993).

Civil society has been important to defenders of free market economics because it suggests the virtues of an economy in

which participants' choices are regulated by their interests rather than their official statuses. In principle, such an economy is able to effectively produce and circulate goods on the basis of prices rather than government direction. Civil society has been equally important to advocates of democracy because it signifies the capacity of citizens to create amongst themselves the associations necessary to bring new issues to the public agenda, to defend both civil and human rights, and to provide for an effective collective voice in the political process. This involves both a free press and political mobilization on the basis of parties and interest groups (see Cohen and Arato, 1992 for the most detailed review; also Chandhoke, 1995; Seligman, 1992; Alexander, 1998; Keane, 1999). Habermas (1992, p. 367) summarizes the recent usage: 'civil society is composed of those more or less spontaneously emergent associations, organizations, and movements that, attuned to how societal problems resonate in the private life spheres, distill and transmit such reactions in amplified form to the public sphere. The core of civil society comprises a network of associations that institutionalizes problem-solving discourses on questions of general interest inside the framework of organized public spheres.' Habermas' work more generally, however, reveals this to be a minimally theorized as well as optimistic usage. It highlights one aspect of civil society but does not make clear the most basic issue.

While part of the heritage of the idea of civil society has been the effort to organize society through public discourse, an equally influential part has been the claim to privacy, the right to be left alone, the opportunity to enter into social relations free from governance by the state or even the public. The idea of business corporations as autonomous creatures of private contract and private property thus reflects the heritage of civil society arguments as much as the idea of a public sphere in which citizens joined in rational-critical argument to determine the nature of their lives together. Civil society refers to the domains in which social life is self-organizing, that is, in which it is not subject to direction by the state. But this self-organization can be a matter of system function or of conscious collective choice through the public sphere (Calhoun, 2001).

Habermas' account of the public sphere drew a variety of important critical responses. One of the first focused on the extent to which he focused on the bourgeois public sphere and correspondingly neglected nonbourgeois public life and failed to clarify some of the conditions built into the bourgeois ideal. Negt and Kluge (1972/1993) responded with an account of the proletarian public sphere. Clearly, workers have at many points built their own institutions, media, and networks of communication, and entered into contention with bourgeois elites and other groups over the collective good. But if this is a discursive competition – that is, if workers and bourgeois argue over what constitutes the collective good rather than only fighting about it – then this implies an encompassing public sphere, albeit an internally differentiated one.

Nancy Fraser (1992) has influentially emphasized the importance of 'subaltern counterpublics' such as those framed by race, class, or gender. Some publics – even very partial ones – may claim to represent the whole; others oppose dominant discursive patterns and still others are neutral. Not all publics that are distinguished from the putative whole are subaltern. As Michael Warner (2001) has suggested, the deployment of claims on an unmarked public as *the* public sphere is also a strategy, generally a strategy of the powerful. Yet, it is important to keep in mind both that the existence of counterpublics as such presupposes a mutual engagement in some larger public sphere and that the segmentation of a distinct public from the unmarked larger public may be a result of exclusion, not choice. Feminist scholars especially have drawn attention to both the gender biases within family life that disempower women and the historically strong gender division between public and private realms on which male political freedom has generally rested (Elshtain, 1993; Young, 2000).

Conclusion

Theories of civil society focus on the capacity for self-organization of social relations, outside the control of the state and usually beyond the realm of family. The basic question posed by theories of the public sphere is to what extent collective discourse can determine the conditions of this social life. Contemporary research on civil society and the public sphere turns on the breadth of political participation, the extent to which capitalist markets limit other dimensions of self-organization in civil society, the existence of multiple or overlapping public spheres, the impact of new communications media, and the quality of rational-critical discourse and its relationship to culture-forming activities. These issues also inform discussions about international civil society and its public sphere.

The concepts of civil society and public sphere took on their primary modern dimensions in the late eighteenth and early nineteenth centuries in Western Europe and to a lesser extent the United States. They have become important in a variety of other settings, including in conceptualizing social autonomy in relationship to communist and authoritarian states. They inform democratic projects as well as academic research in a variety of settings and are in turn themselves informed by cultural creativity and social action.

Abstract

Historically, the idea of civil society has taken two very different forms. In the first, civil society is 'political community' (*societas civilis* or *koinonia politike*) encompassing a state undifferentiated from society. Here, civil society is coterminous with the state – that is, power relations ordered through law and institutions with the objective of ensuring social harmony. In the second, civil society is a self-regulating, self-governing body outside and often in opposition to the state, represented both as the nexus of societal associations expected to generate civility, social cohesion, and morality, and as the site of reciprocal economic relations among individuals engaged in market exchange activity. The article, emphasizing social, economic, and state transformations between the sixteenth and the eighteenth centuries, focuses on the differentiation in social and political theory, between state and civil society. Since the nineteenth century, this differentiation has been a leitmotiv of Western political discourse notwithstanding the blurring of the lines between state and society amid social and political struggles out of which emerged the social states (Bismarckian welfare state), corporatist states, between the two world wars, and the Keynesian welfare states.

Historically, the idea of civil society takes two very different forms. In the first, civil society is 'political community' (*societas civilis* or *koinonia politike*) encompassing a state undifferentiated from society (Ellis, 2000). Here, civil society is coterminous with the state, that is, power relations ordered through law and institutions with the objective of ensuring social harmony. In the second, civil society is a self-regulating, self-governing body outside and often in opposition to the state, represented both as the nexus of societal associations expected to generate civility, social cohesion and morality, and as the site of reciprocal economic relations among individuals engaged in market exchange activity.

Koinonia Politike and Its Historical Modulations

In Greek and Roman political thought, the notion of civil society as political community was not limited to the legal category of citizenship. Central to Aristotle's (384–22 BC) conception of political community was the recognition that people lived in different social spheres and their status varied in terms of property, skills, and abilities. The art of politics was the use of laws and institutions to organize activities within these different spheres with the objective of attaining a harmonious or 'just' social environment. Aristotle regarded the citizen as one who shared in the administration of justice and held office to this end (Aristotle, 1965). In this sense, citizenship in the Athenian city-state was as much a moral as a legal category (Ehrenberg, 1999). The household was not excluded from Aristotle's moral scheme. Household subsistence production was 'natural,' while production for commercial exchange and profit was 'unnatural' and subversive of the moral order. The exercise of justice presupposed constraints on commercial activity.

For Cicero (106–43 BC) and the Roman lawyers, civil society (*societas civilis*) was the equivalent of *res publica* (commonwealth), or "an assemblage of people in large numbers associated in an agreement with respect to justice and a partnership for the common good" (Cicero, 1988). Cicero viewed justice as rooted in man's natural 'social spirit,' which was informed by reason and induced individuals to forego a measure of self-interest in the interest of common good (Ehrenberg, 1999). Cicero was writing when Rome had ceased to be a harmonious 'commonwealth' run by its citizens and their subsistence-producing households, but had become an imperial city in which landowners, financiers, and merchants coexisted uneasily with a vast and hungry population of peasants and slaves. Cicero saw the realization of justice as the "even balancing of rights, duties and functions" within the state (Cicero, 1988). *Societas civilis* thus represented groups and individuals united by laws and institutions, which organized their activities and sought to achieve a flexible equilibrium among them.

Until the end of the eighteenth century, the various societies of Western Eurasia generally conformed to the Aristotelian model of a politically constituted moral community. In Western Europe, however, the idea of *koinonia politike* virtually disappeared during the Middle Ages when extreme political fragmentation led to the Church assuming a central role in government and social life.

On the other hand, in the Byzantine Empire, the idea of a politically constituted community persisted and the Church was subordinated to the political and moral authority of the emperor. The Ottoman Empire succeeded to this mode of political discourse, but added ideas of bureaucratic and hierarchical organization derived from the political traditions of the agrarian empires farther east, notably Persia. This synthesis, which predated the Ottomans, was formalized in the ninth and tenth centuries by Islamic philosophers well versed in the works of Plato and Aristotle, as well as by the bureaucratic elites of the Islamic states who were educated in the Persian tradition. It was resisted by some sections of the Islamic establishment on the grounds of the equality of all before God. The ensuing power struggles did not, however, result in an autonomous

'Islamic Church,' but rather the religious establishment was subsumed within the political hierarchy.

In the Ottoman Empire, *koinonia politike* was epitomized by the figure of the just ruler, whose ability to establish 'good order,' or *shariah* in the Islamic sense, predicated upon an absence of social strife, constituted justice. Exercise of justice involved laws and institutions accommodating different interest groups in order to sustain the conditions for household subsistence production and to achieve equitable distribution of resources among power holders. Thus, laws and institutions represented negotiated settlements between the ruler and different interest groups.

In Western Europe, the idea of community created by God and comprising all mankind (i.e., all Christians) was a challenge to the notion of differentiated community constituted through politics to achieve social harmony and justice. St Augustine's *City of God* (*De Civitate Dei*, 413–26), where men were equal before God and united in the universal church, stood in contrast to the Greek and Roman *polis* of differentiated spheres of life. The Church and the temporal rulers responsible for its government derived their right to rule from God and stood outside the community.

However, struggles between the Church and temporal rulers, coinciding with the rise of monarchies, resulted in the division of social activities into spiritual and temporal spheres governed, respectively, by the Church and the kings. The concept of *koinonia politike* found a new foothold in the institution of monarchy. Between the fourteenth and seventeenth centuries, European monarchs, endowed with divine right and with absolute powers, nevertheless engaged in constant negotiations with different interest groups. Political society rested on the exchange of entitlements to different groups and individuals in return for their obedience and/or services they rendered.

Koinonia Politike Transformed

In the sixteenth and the seventeenth centuries, following a period of religiously driven civil wars, the idea of a Christian *koinonia politike* was replaced by the concept of the overriding sovereignty of the secular ruler who subordinated religious claims and restored peace. This was the Hobbesian moment in which the modern state rose to define, limit, and enforce moral alternatives to God's order (Maier, 1987). Competition among European monarchies, warfare, civil war, and peasant uprisings all contributed to centralization of political power. By the end of the seventeenth century, this was reflected in the institution of the sovereign monarch as a site of bureaucratic administration and regulation. Commercial expansion in the seventeenth and eighteenth centuries meant that economic activity became a primary target of state regulation. The administrative, regulatory state was represented in discourses on economic administration that combined cameralism, mercantilism, political arithmetic, and bullionism.

Thus, political or civil society was no longer the politically constituted community characterized by a diffusion of political power. Instead, political society referred to the sphere of absolute sovereignty. Social harmony, which remained the legitimizing objective of rule, was the product of bureaucratic regulations and no longer the outcome of reciprocal exchanges or negotiated settlements between the ruler and the different sectors of society.

Attempts to formalize the sovereign state also had the effect of pointing to the existence of a sphere outside the political domain. In the latter part of the eighteenth century, a new conception of civil society as the site of self-regulation developed, referring to voluntary associations freed from the corporate grip of the Church and urban institutions and to the sphere of economic activity. This concept of a self-regulatory, self-governing society was often in opposition to the regulatory, political domain of the state.

The dichotomous conception of state and civil society, was, however, preceded by the distinction in Natural Law theory between *status civilis* and *status naturalis* (Tribe, 1988). The latter was the sphere of discord that the English philosopher Thomas Hobbes (1588–1674) described as *bellum omnium contra omnes* – barter society in which individuals contracted with and against one another (Hobbes, 1949), and to which his countryman John Locke (1632–1704) assigned the contentious process of the formation of private property. For Hobbes, the state of nature ended when it submitted to the 'civil union' 'called state or civil society'. For the Prussian Cameralists of the same period, organization of economic activity in political society, or its regulation, ensured the security and prosperity of the commonwealth, including providing the population with subsistence and productive employment. For the English mercantilist, James Steuart (1712–90), self-interest had to be restrained and directed by the 'reason of state' if it were not to damage public good, which he defined in terms of England's increasing commercial success.

Concentration of political power in administrative monarchies had resulted in a decline in the importance of the corporate bodies and deliberative institutions that had earlier served to mediate power. Groups that were excluded from the political process, as well as new bureaucratic elites and commercial classes, sought inclusion through societal associations and political institutions that could provide them with a voice against absolutism. In France, Britain, and Germany, respectively, Montesquieu (1689–1755), Ferguson (1723–1816), and Kant (1724–1804) proposed conceptions of civil society focused on delineation of associational spaces, of environments for societal negotiations, of civility, and of publicity (Jacob, 1991).

Responding to the despotism of the eighteenth-century French ancient regime, Montesquieu saw in civil society (*l'état civil*) a context for the societal negotiation of the absolute power of the monarch that was not a domain separate from the monarchy. His concept of division of powers addressed a situation in which the monarchy had severed itself from the network of power relations within the political society and had appropriated for itself a separate sphere of power (*l'état politique*). It sought to reintroduce the monarch into the *l'état civil* by means of institutions that would check the absolute authority of the ruler and balance it against the authority of the landed aristocracy, their advocates in the judiciary, and commercial interests (Richter, 1998).

Kant first employed the notion of civil society, or *bürgerliche Gesellschaft*, in the sense of political society inseparable from the Prussian absolutism of Frederick the Great (1712–86),

which he considered indispensable for social stability. Second, *bürgerliche Gesellschaft* referred to the public sphere or a domain of literate citizenry that was separate from the arena of political power and action. Kant regarded the political arena as the reserve of the state, or the ruler. *Bürgerliche Gesellschaft* referred to a sphere 'beyond the political order,' 'beyond the particularistic concerns of political action' where practical issues of governance could be debated on the basis of universal principles of reason. For Kant, the critical practice of exposing actual state policies to the light of universal reason could act to restrain the absolute power of the ruler as well as legitimizing his power (Ellis, 2000). Kant's *bürgerliche Gesellschaft* was composed of individuals from the Prussian bureaucratic and bourgeois elites, educated and trained in state schools and administrative offices, as well as members of social clubs and associations, who could by dint of reason rise beyond the trappings of class or official status.

The thinkers of the Scottish Enlightenment who addressed the issue of civil society did not limit themselves to the issue of restraints to centralized state authority. Adam Ferguson pointed to the corrosion of civic spirit in political society, where the successful commercial classes became servile to the administrative state, which provided them with a 'rule of law' but deprived them of their traditional rights (Keane, 1988; Ferguson, 1995). He conceived of civil society as networks of self-governing and self-regulating voluntary associations, such as self-help groups and 'friendly' or charitable societies, which had expanded rapidly in the eighteenth century and, in Britain, played an important part in poverty relief efforts. Ferguson pointed to the potential of voluntary associations for engendering civility beyond the special interests of state administration and the commercial classes. The central question facing Ferguson and other eighteenth-century European thinkers was how society increasingly differentiated administratively and economically, could remain integrated and harmonious. For Ferguson, as for his compatriot, David Hume (1711–76), civility was the basis for social cohesion, and he saw it as rooted in sociability or moral and emotional communication among persons "that fostered social bonds and friendships and cultivated manners and moral tastes" (Trentmann, 2000). Ferguson did not place civil society in opposition to the state; rather, civil society constituted a protective shield from the uncertainties of social and political life.

Civil Society as a Separate Domain

For Adam Smith (1723–90), also a thinker of the Scottish Enlightenment, civilized society consisted in self-regulating and interdependent networks of economic relations among individuals and groups, originating in the decisions of individuals competing in markets for goods, labor, and capital. Economic activities of self-interested individuals were guided by the universal, natural laws of supply and demand. For Smith, the civilizing of economic society and the harmonizing of individual interests presupposed a mode of sociability and reciprocal sympathies among individuals (Trentmann, 2000).

Smith proposed a separation between the civilized society of economic activity and the political sphere of the state and insisted on the liberation of labor, capital (including land), and goods from the network of relations of political society. The doctrine of *laissez-faire, laissez passez*, first introduced by the eighteenth-century French Physiocrats and taken up by Smith, was a plea for the removal of regulations that privileged the landed classes through restrictions on the grain trade, merchants through grants of monopolies, and the 'poor' through grain subsidies provided by the Poor Laws. Smith was an advocate of the new industrial order and opposed to regulations that represented interventions by the state in the economic process, including the free exchange of labor, capital (including land), and goods.

Smith argued that if individuals, unimpeded by privilege and state regulation, could act in accordance with their self-interest, markets could be trusted to allocate resources equitably in the form of wages, rents, and profits. This, for Smith, was the key to progress, economic growth, and national prosperity (Smith, 1974). On the other hand, he was not entirely indifferent to the dislocations generated by markets and he assigned the civil state the duties of administering justice and providing security, including the protection of private property and correction of severe inequalities created by market forces.

Smith's civilized society, like Ferguson's civil society, Kant's *bürgerliche Gesellschaft*, and Montesquieu's *l'état civil*, represented positive images of civil society, which, in the course of encounters with hitherto unknown regions of Asia and the Americas during the seventeenth and eighteenth centuries, became part of Europe's definition of itself as the domain of the 'civilized' (Kocka, 2000). The discourse of civilized Europe created its opposite in images of an uncivilized non-Europe, notably the East, which was perceived as the domain of despotism *pace* Montesquieu, of chafing regulations over economic activity *pace* Smith, and of the absence of private property *pace* Marx. Following the last decade of the eighteenth century, with the onset of revolutionary upheavals against absolutist regimes, the terms *bürgerliche Gesellschaft* and civil society were increasingly equated with bourgeois society and acquired a negative connotation as 'the reign of dissoluteness, misery, and physical and ethical corruption' (Hegel, 1967; Kocka, 2000). The European idea of itself as 'civilized' was effectively distanced from understandings of civil society as bourgeois society. No matter how 'barbaric' Europe became in Europe, it would remain 'civilized' vis-à-vis non-Europe, its optimistic image of itself having been fixed in a vocabulary of domination.

Hegel (1770–1831) responded to this situation with the idea of the universal state that was to end the separation between the political and the economic. He subscribed to the political economists' notion of civil society as a nexus of economic interests and relationships that continuously reproduce themselves. He did not, however, share Smith's utopian faith in the mechanistic operations of the market. Revolutionary upheavals had revealed a discrepancy between models of an orderly economy subject to universal laws of nature and the chaotic reality of contemporary society. Conceptualizations of civil society as an autonomous domain capable of generating order and progress through its own dynamics now appeared dubious.

Hegel's civil society was not the civilized society of Smith, but bourgeois society that manifested extremes of wealth and poverty that threatened to destroy the productivity of

individuals pursuing their self-interest (Reidel, 1984). The destructive potential of civil society, he felt, could be restrained through redirecting individual self-interest by administrative means, including justice, police, and moral measures.

Marx (1818–83) subscribed to Hegel's critique of political economy and his conception of civil society as an arena of self-interest and divisiveness with a potential for self-destruction (Bottomore, 1983). But unlike Hegel, Marx was not concerned with the containment of bourgeois society's destructive potential. Instead, he focused on the revolutionary transformation of economic relations in civil society, which he believed was possible through the mobilization of conflicts between different interest groups. For Marx, the state, distinct from civil society or *bürgerliche Gesellschaft*, is largely limited to formalistic and negative activities since in his view, civil society both preceded and determined the state. Civil society required no regulation but was ruled through the contingencies of class struggle.

Civil Society and the Liberal State

Political and academic debates of the nineteenth century addressed the question of how to achieve social stability in market societies where the logic of economic activity overrode moral and political concerns regarding equity. Civil, or liberal, society was perceived as a domain shaped by or reformed through the practices of a central state representing the public interest. This constitutes a major departure from eighteenth century thinking. On the one hand, civil society, its actors, its activities, and the economic relations that characterized it, were viewed as inseparable from their legal and administrative formulations. This resulted in the creation of legal entities including trade unions, corporations, and family, and of voluntary and charitable associations, which, while autonomous from the state, remained within the bounds of its administrative–legal vision (Neocleous, 1996). On the other hand, the state, 'objectified' in its administrative and legal practices, was understood to stand apart from civil society and to mediate divergent interests and needs.

From the perspective of the English utilitarians, most notably Jeremy Bentham (1748–1832), and of the German social economist Lorenz von Stein (1815–90), civil society, or the market economy of the political economists, needed to be actively constituted. It was not enough simply to remove the obstacles of obsolete privilege and restrictive policies of mercantilism of the *ancien régime*. For Bentham, the new economic order required positive state intervention, and government was inseparable from an "art of directing the national industry to purposes to which it may be directed with greatest advantage." Von Stein, agreeing with Hegel's perception of civil society as a site of conflict and oppression, identified the 'social problem' as the main obstacle to economic progress. Progress required a market economy, or civil society; however, the injustices and inequalities it generated must be ameliorated through the state's administrative activity. The creation of social citizenship and the active participation of the citizen in the state's decision making were central to this process (Pasquino, 1981). Thus, civil society represented an outcome of collective struggles and clashes among divergent interests that were mediated through the state's administrative practices, so that for von Stein, as for Bentham, the state was not the *Rechtsstaat* ('rule of law' state) that stood outside civil society, but the *Sozialstaat* (social state) representing a process whereby society was continuously formed and reformed.

Not all observers of nineteenth-century Europe saw the centralized administrative state as the liberator of civil society. Conservative Romantics rejected the notion of the state or politics shaping society and assigned self-policing power to society and church. Alexis de Tocqueville (1805–59) in his *De la democratie en Amerique* (1835–40) saw the real danger to modern society in the new despotism of the all-pervasive state administrations rather than in class conflicts. Anticipating his fellow Frenchman, Michel Foucault (1926–84), de Tocqueville pointed to the administrative suffocation of civil society as evidenced in the state's monopoly of public education, health care, and social services to the poor and unemployed that subjected all aspects of citizens' lives to state scrutiny (Keane, 1988). De Tocqueville stressed the importance of voluntary associations in placing checks on administrative despotism by providing the services that people expected from government, thus preempting government intervention in civil society. Recalling the ideas of the Scottish Enlightenment, de Tocqueville saw voluntary associations as generating and expressing community civic values.

Civil society all but disappeared from political and academic debates in the late nineteenth century and the period following World War I, a time of slackening economic growth, rising working-class activism, imperial rivalries, and wars, which witnessed the displacement of political power from state administrations to major organized groups in society. The European welfare states, heirs to the liberal states, increasingly became sites for centralized and bureaucratic bargaining among political parties, labor unions, and business cartels vying for economic and political power and blurring the distinction between state and civil society, public and private (Maier, 1987).

Antonio Gramsci (1891–1937), leader of the Italian Communist Party, represented a notable exception to the lack of interest in the notion of civil society in the post-World War I era. He reformulated the Marxist–Hegelian understanding of civil society in terms of the corporatist Zeitgeist of Italy in the 1920s. For Gramsci, civil society was not merely the sphere of individual needs but also of organizations where the hegemony of the ruling class and consent to that rule was negotiated. In this sense, civil society comprised not only all material (economic) but also political and cultural relations. While Marx insisted on separation between state and society, Gramsci held the two were interrelated. Hegemony, which was basic to Gramsci's notion of civil society, presupposed 'interpretations' of the economic structure, that is, the political and cultural mediation of different interests (Bobbio, 1988). In that sense, Gramsci had a kindred spirit in Hegel rather than Marx.

Late-Twentieth Century Understandings of Civil Society

After World War II, the European political and economic order focused politics on the state with welfare states

subsuming civil society to state regulation. As in the late nineteenth century and the post-World War I era, economic growth, distribution, and security represented the core themes of politics. However, now these themes were generalized to regions outside Western Europe, including Eastern Europe and postcolonial societies in the so-called Third World. The different regions varied greatly in terms of how growth was attained and sustained, and the efficiency of realizing their economic and social goals.

They also varied in terms of their political institutions and modes of resolution of social and political conflict. From the late 1940s to the mid-1970s sustained economic growth in the capitalist economies of Western Europe and North America made challenges to economic redistribution less urgent, and the internationalization of the security problem (e.g., the formation of North Atlantic Treaty Organization) led to a consensus regarding security. Capital transfers from a booming United States economy, including military and economic aid, helped to sustain the developing states of the Third World, while the statist socialist regimes relied on the ideological and political disciplining of their populations to generate surpluses centrally distributed by the state.

During the 1950s and 1960s, some social scientists in Western Europe and the United States predicted that under conditions of long-term growth, political problems could be largely transformed into noncontroversial administrative routines resolvable by experts. Socialist regimes perfected this functionalist perception of politics where government excluded all competing forms of political organization, including political parties, trade unions, and collective bargaining. However, this perspective precluded discussion of civil society. Socialist ideologues identified civil society with bourgeois society and held it was superseded by the advent of socialism.

In the mid-1970s, slowing economic growth in the advanced capitalist societies resulted in constraints on the ability of the state to tax business and distribute assistance to the working class in the form of social welfare benefits. The fiscal crisis was further aggravated by rising costs of welfare provisions, and called into question the validity of ideas that subsumed society to state regulation. Since the 1970s, social and political debates have largely focused on the critique of social statism and the differentiation of civil society from the state.

From a neoconservative stance, overpoliticization of the state and the fusion of political and nonpolitical spheres of social life has eroded political authority, weakened governability, and destroyed the autonomy and authority of nonpolitical spheres, including family, religion, and the market. Neoconservatives proposed the boundaries between state and civil society be redrawn. Civil society, in opposition to the state, represented the depoliticized sphere of market activity and all else, including religion and family. It should be reintegrated through a cultural model that cohered the exchange activities of self-interested individuals. This is a model of the self-regulating civil society of nonprofit voluntary associations reminiscent of the eighteenth-century Scottish Enlightenment. During the 1980s and 1990s, social science paradigms based on individual self-interest and rational expectations presented models for social programming that would render a politicized civil society unnecessary. In the neoconservative view, the state is a lean structure characterized by effective authoritarian forms of action, approximated by its Thatcherite interpretation in 1980s Britain.

For proponents of the voluntary social movement paradigm, statism had disastrous environmental, political, and social consequences. They proposed an understanding of civil society as an autonomous politicized sphere independent of regulation and constraint by bureaucratic political institutions. Social movements such as the environmentalist, antinuclear, and women's and gay movements of the 1970s, were politically motivated by concerns about the environment and quality of life, and issues of equity, authenticity, and participation. Their agendas required 'spontaneous' organization and not 'officially' sanctioned institutions of political parties and trade unions. Here, civil society referred to an intermediate institutional space between private (personal) and public (the object of official political institutions and actors).

Jurgen Habermas' (1929) idea of public sphere parallels this understanding of civil society in the context of ideas and communications; it includes the organization of civic or bourgeois opinion as represented by associations and media. Public sphere is a space where communication about collective values takes place. In advanced capitalist societies where political and economic domains merge, the state became a major actor in the market economy and thus no longer able to advance the common good. This, for Habermas, signals the legitimation crisis of advanced capitalist societies and raises the issue of the formulation of a public discourse outside of the spheres of market economy and the welfare state and in doing so (in the spirit of Kant), subjects both spheres to the critical scrutiny of communicative rationality.

In the mid-1970s, the crises in socialist states, initially Poland, provoked Central and Eastern European intellectuals to address the issue of the politicization of civil society. After failed revolutions in Hungary (1956) and Czechoslovakia (1968), the new evolutionism of Adam Michnik and Jacek Kuron proposed the bottom-up construction of a civil society to repulse state intrusions into social life. For other dissident socialist intellectuals in the region, most notably Vaclav Havel, civil society represented the domain of antipolitics; it was a vision of society not simply independent of the state but opposed to it.

During the 1980s and 1990s in many parts of the world, including the former socialist states of Central and Eastern Europe, the expansion of the market system, including privatization programs, led to two divergent perceptions of civil society. The first represented civil society in opposition to global capitalism and to the state as the implementor of market reforms. The second emphasizes the centrality in civil society of religion, family, and voluntary associations for generating moral, economic, and cognitive norms.

Abstract

This article summarizes the social and especially political science literature as it pertains to the wave of civil or internal wars which have emerged since 1945. It does so by; (1) asking how well the concept of civil war travels, (2) locating this literature with the general treatment of war and revolution historically, and (3) discussing the nature of causality and the recent reliance on purely structuralist accounts of civil war.

Only recently has the study of civil war become a specific subfield within social science, a development reflecting the fact that as war between states became rarer after 1945, civil wars have proliferated. The dominant historical attitude was disapprobation. Civil wars threatened both the collapse of states and those social relations that made states possible. Between the French Revolution and the end of the Cold War, civil wars were also treated as appendices to other forms of war, such as interstate war. Only the end of the Cold War opened up a vista for civil war studies in their own right. Scholarship became less overtly partisan, the connection with colonial legacies intriguing, and a strong emphasis placed on the consequences in terms of economic underdevelopment, state collapse, population displacement, and human rights violations. A huge literature has also emerged on establishing peace.

The Concept

In an influential definition Small and Singer (1981, p. 201) considered civil wars as armed conflicts which involved military action internal to the metropole, with government participation but effective resistance by both sides. Such wars were different from wars that involved external intervention or resistance to colonial rule by virtue of their internality: the domestic government was involved and fighting was on its sovereign territory. By adding the criterion of a threshold of deaths, (to exceed more than 1000), one could distinguish civil from other forms of internal war.

Such a definition defines civil war in terms of its necessary elements and allows for comparison between a large number of cases. Yet it considers as one conflicts leading to total polarization within a state and insurgencies which do not. Conflicts which occur within an integrated political community, and those where no such community exists at the outset of conflict, are also conflated. The problem is one of 'lumping' types of conflict together, rather than 'splitting' them into different subtypes in order to reveal distinct characteristics.

The issue is how well civil, an adjective given elevated status only in the West's political thinking, actually travels. In Europe, the essence of civil war was presumed to lie in this civil character. The German concept of *Burgerkrieg* reflects the idea of civil war taking place within a society of fixed social orders (Brunner et al., 1972). It suggests that civil refers to the participants. This continued the Roman way of categorizing wars in terms of the enemy being fought: to them we owe the term civil war (*bellum civile*) (Armitage, 2009). Civil has as antonyms military and ecclesiastical, and can pertain to the community, ordinary life, or individual citizens. In law it covers private relations among citizens. Within this sphere civil life can flourish, but conflict between citizens also produces the worst polarization. The Roman conception is still influential. The Chambers English Dictionary defines civil war was simply as a war between citizens of the same state.

Kalyvas (2006, 18) sees two further ways of thinking about the civil in civil war which have wide application. The first, rooted in the Greek historian Thucydides, focused on the split nature of the polity, and reflects different groups controlling different territories, or rival claims to sovereign authority. The second, which emerged in larger entities such as Empires, uses concepts of sedition and rebellion to characterize civil war. Hence the focus on legality. Thus in England a distinction emerged between rebellion, which was an action against an established authority without legal justification, and revolution which meant the restoration or renovation of an earlier lawful authority. Cromwell's actions were first seen as the Great Rebellion, while the events of 1688 were termed the Glorious Revolution. These ideas are not obsolete. In Costa Rica, the idea of civil war as a means of restoring a constitutional *status quo ante* had a powerful influence on the outcome of the 1948 civil war. In Rwanda however, the split nature of the populace is far more important than any constitutional framework. Yet the American civil war emerged in a split polity, under a constitutional framework invoked by both sides as a source of legitimacy. It was a civil war in both senses.

In ancient Greece and Rome, civil conflicts threatened afixed social orders. The French Revolution changed this, and by mobilizing the nation in arms, made the people as a whole the collective agent. Civil war ceased to be defined as a war among citizens of a city, country, or state, but became a war of a part of a nation against another, or a war among hostile parties 'within the same state.' Hence the link with fratricide. What first set it apart from other conflicts was the concept of citizenship (promoted by the French Revolution, but reviving an old Roman idea). Yet modernization soon broke up those fixed orders and established state and civil society as the two

poles around which contemporary politics were organized (Brueilly, 1996, pp. 164–169). Civil war would happen between those poles. For Carl Schmidt (1996), the state's primary role was to make sure that the total enmity of 'friend enemy' distinctions in interstate wars would not be reproduced within the state. His greatest fear was thus of internal war.

Internal war became a concept used by political scientists in the 1960s (Eckstein, 1965). The neutrality of the term suggests that civil war was an internalized form of war in general. The Cold War was the crucial backdrop, since after 1945 all wars were transformed into civil wars (Koselleck, 2004, p. 56). The Stanford Encyclopedia of Philosophy defined war as "an actual, intentional, and widespread armed conflict between political communities": civil war, between rival groups or communities 'within a state,' is its internal variant (Orend, 2008 Eckstein used 'internal war' as a generic term, with civil wars, coups, riots, rebellions, massacres, and revolutions, species of it. This concept could include conflicts not considered 'classic' civil wars, and avoided the problem of legitimizing all internal wars as 'civil wars' (Payne, 2011, p. 5).) The internal war conception appealed in a world where territorially concentrated insurgencies against the state became its typical form. There was a 'spontaneous' type, where violence occurred without much leadership and planning, and provided opportunities for the seizure of power. These occurred mainly in societies with no tradition of stable institutions within which political changes could take place. The more common 'planned' type – where channels for the settling of grievances are blocked – involves an attempt at seizing power violently, involving a guerrilla group and an organized campaign. This assumes some centralized power as a starting point (International Encyclopaedia of the Social Sciences, 1968, p. 499).

Eckstein wanted the internal war conception to facilitate comparative analysis of conflict transformation (how terrorism became insurgency for example). This could not be done by categorizing conflicts into distinct types in advance. Yet what makes them internal in the first place? They were conflicts 'within a society' that usually resulted from an attempt to seize power and symbols of legitimacy by extralegal means. For Renzato (1994v) 'internal war' takes place within a state or a city, among citizens of the same state or city, as opposed to external war that is fought between sovereign states. Brown (1996) sees them as conflicts whose origins are *primarily* due to domestic rather than international factors, and in which violence takes place *primarily* within the boundaries of a single state. Others stress that the government must be a protagonist, with control of the state the key objective for both parties. Hence, the struggle for legitimacy is crucial, unlike in conventional interstate wars, where the status of the opposed states is usually uncontested. The stress on legitimacy is consistent with Clausewitz's conception of war as politics by other means.

The internal war approach was appropriate to a world where decolonization had created more than 120 new states, and when the nuclear standoff during the Cold War had created an international environment in which more internal war took place. Yet these were often proxy wars, where the boundaries between internal and external politics were actually porous. Going back as far as Thucydides, the worst consequences of internal wars often result from the involvement of external powers. In the 1990s, doubts then emerged about the robustness of both state and nation in an era of globalization. The 'New Wars' literature refers to a type of war which developed in Africa and Eastern Europe in the 1980s and 1990s. Their newness consists in blurring the boundaries between war, organized crime, and large-scale human rights violations (Kaldor, 1999, p. 2). Such conflicts are not necessarily fought for political ends (to acquire state power). Related concepts: 'wars of the third kind,' 'complex emergencies,' 'postmodern wars,' and 'never-ending wars' suggest rather a blurring of categories, between combatants and noncombatants, between war and humanitarian crises, and between periods of war and peace.

The approach is especially relevant to interethnic wars which are fought between citizens of the same state, but often take the forms of interstate war; with regular armies, battles, and soldiers in uniforms. The substitution of 'new' for civil reflects 'the erosion of the state's monopoly of violence' (ibid, 40), from above by the growth of international military forces, and from below by transnational crime networks, diasporas, and paramilitary actors. Indeed the paramilitary has become the embodiment of such new wars. Bosnia Herzegovina is the paradigm case. Such wars "are part of a process which is more or less a reversal of the processes through which the modern state evolved" (ibid, 5). Historically, as the modern state developed, it grew through war and had to mobilize domestic resources to finance this effort. As war became the province of the state, and competitors to the state were eliminated, its growing destructiveness was accompanied by growing security at home: "hence the way in which the term 'civil' came to mean internal" (ibid). This distinction between internal and external politics had allowed for a sphere within which civil wars could occur. As it collapsed civil war has ceased to be a major category of warfare.

The new wars approach reflects the tendency for conceptions of civil war to reflect the regime trends of their era. It is appropriate to a world where many states were failing, just as the ancient Greek concept of 'stasis' (faction or the consequences of faction) reflected an acute sensitivity to the morphology of states (de Romilly, 1991). The newness of such wars is debatable, but if neither state nor nation is ontologically robust, the question it raises is whether concepts of conflict assume an integrated political community for them to be categorized as civil or internal. Kalyvas (2006, 17) wants civil war to remain the master concept, which encompass peasant rebellion, ethnic insurgency, revolution, and anticolonial wars. 'Civil' refers primarily to a divided polity, but the people must also be members of a common community at the outset. If so, the relationship between state and nation usually defines what is civil new or internal about domestic conflicts.

The Literature

Civil wars are ubiquitous in human history, but little has been written systematically about them. What exists reflect different intellectual traditions. On the English civil wars of the seventeenth century, historians stress constitutional factors as the prism through which the conflicts should be viewed. In contrast, Thucydides (1910) focused on the psychological

consequences of internal strife, believing constitutional ideals were pretexts for other (venal) ambitions. In his study of the Peloponnesian Wars he sees stasis as resulting in a deterioration of manners and morals, as a war between two city-states became the vehicle for personal ambition and an occasion for private vengeance.

Civil war has always suffered from comparisons: nowhere in nineteenth-century Europe was the almost universal approbation of war applied to civil war. With the emergence of the modern conception of revolution, civil war was also left bereft of a positive connotation. It invoked the religious wars of the sixteenth and seventeenth centuries, with their hatred and blind fanaticism. The idea that revolutionary violence could legitimately be motivated by understandable political grievances, also contrasted with the fanaticisms of such wars. Thus while revolution promised change, after 1789 civil war acquired rather the meaning "of a senseless circling upon itself, with respect to which Revolution sought to open up a new vista" (Koselleck, 2004, p. 49).

The negative judgment also reflects the simple conviction that war within is worse than conflict with an external enemy. Aggression that comes from close by is more harmful and more likely to transgress norms. Yet the contrast also reflects a persistent tendency to romanticize wars fought by states. Such wars, being fought by regular armies, subject to greater centralized control and doctrines of war, are somehow less barbarous. The fact that such contrasts are always made (without testing them) shows the extent to which our understanding of what is political has been shaped by the modern state. Only for internal wars do we ask *Why Men Rebel?* (Gurr, 1970). We never do so for interstate wars, whose political rationality is conferred upon by the participation of the state.

The treatment of civil war in the history of Western political thought has been sporadic. We have no treatise to compare with Burke's reflections on the revolution or Kant's on peace. In the Greek city-states, when systematic thought on the nature of power flourished, the concept of stasis suggested that fragmentation was the worst consequences of civil war. The Romans also tended to see the succession of civil wars which led to the establishment of the Empire in the first century B.C. in terms of a deterioration in public life. Both show that the contribution of civil war to the history of political thought has largely been to make people reveal their vision of the good society when faced with the challenge of reconstruction (MacIntyre, 1971, 132). One example is Hobbes vision of a Leviathan based on obedience and protection. What is ours?

During the Cold War most universities taught courses on revolutions. Special attention was placed on big cases, such as the French Revolution, linked to ideas of social transformation, or those like the Iranian Revolution of 1979, which left their mark on the international relations of the era. Little systematic attention was paid to civil war, despite it often being the 'hard nucleus' of most revolutions in reality. One school of thought attempted 'a natural history of revolutions' which they thought went through regular patterns and cycles, This was very similar to current scholarship on processes of polarization, radical or deradicalization, and mobilization. Later scholars used comparative historical analysis of a small number of cases to identify preconditions for revolution, and this work on crises and state breakdown has been extended to more recent civil wars (Goldstone, 2009).

There was also an urban bias. Everyone has heard of Che Guevara, Malcolm X, and the Baader Meinhof. The lack of attention to rural insurgency was rectified by the 'internal' wars approach which continues in the form of large N research today. Yet the fundamental catalyst for the growth of this field was the end of the Cold War. The collapse of Yugoslavia refocused the attention of security studies onto domestic sources of conflict. Moreover, as many Soviet experts found themselves unemployed, the end of the Cold War revealed that the number of domestic conflicts had actually been steadily accumulating since the 1940s. What was striking about many proxy wars, such as in Southern Africa, was that they lasted for decades. As a consequence, there was a revival of interest factors that made the new states vulnerable to internal wars: the connection between ethnic diversity and violence, the concept of state weakness, and the 'conflict trap' spoken about by development economists were explored.

The literature on revolution focused on big cases. Even those which emerged on the world's periphery (China, Mexico, Turkey, and Russia) set in train processes which have taken more than half a century to work themselves out. In civil war studies attention focused poor and formerly colonized territories in Asia and Africa where civil war was seen as a problem for political development. Whereas the standard curriculum 30 years ago included the Spanish civil war, or Fascism, the imagination of students of conflict is now captured by parts of the world very remote from their experience. This has meant that any serious research requires fieldwork, language acquisition, and that a blurring of boundaries between conflict and development studies has taken place. Many influential studies have been done by economists. Some still argue for a longer-term perspective on legacies of imperialism and slavery (Richards, 2008), but the general interest has been in structural factors that make these new states vulnerable to conflict after independence.

Thus since 1989 the field of civil war studies has acquired a North–South perspective, as that of revolution did during decolonization. The globalization of news media and the number of international organizations involved in crisis management have led to a whole subdiscipline in 'conflict and peace' studies. The terminology of 'complex emergencies,' 'crisis states,' and 'humanitarian disaster' reflects this. A specific literature on peace agreements, post-civil war democracy, transitional justice, and reconstruction has also flourished. Here, the gap between the academic and the policy worlds is becoming narrow. Subdisciplines like that on transitional justice, first concerned with the legal aspects of war to peace transitions, now take nearly every legacy of conflict within their remit. Normative perspectives are strongly in debt to Western liberalism and raise questions uneven power relationships in the academic world. Scholars from poorer countries are reduced to the role of mere suppliers of data in an international division of scholarly labor, which privileges theorists from Western countries whose *recent* historical experience has not been one of internal war.

Methodologically, case studies remain the norm, but the more prestigious political science journals focus almost exclusively on cross-national statistical studies. These trace patterns

of conflict globally, but few good theories on the regional or international sources of civil war exist. There is almost no importance attached to ideology. The general assumption is that the sources of civil war are primarily internal. Yet some landmark books focus not on causal analysis at all, but on the changing nature of warfare, the variation in violence within conflicts, and whether conflict retards development or not (Cramer, 2006; Holsti, 1996; Kalyvas, 2006). Are the actual causes of civil war may too numerous too complex for theoretical treatment in comparative studies?

The Causes

Mainstream causal theories usually try to go beyond the focus on bad leaders where the blame game usually begins. This was true of the American civil war, after which explanations, conspiratorial in character, soon flourished. The collapse of Yugoslavia was also blamed on the behavior of politicians like Slobodan Milosevic, although subsequent studies have tried to specify the conditions under which such demagogues hold sway. An emergent field explores the connection between regime transitions in general, elections, and civil war (Hegre et al., 2001).

Manifestations of conflict can be explained either by the motives of which the quarreling parties are conscious, or by objective situations and processes – in the latter tradition: "we try to explore the unconscious complexes to which these motives relate like mere symptoms of an illness to the organic disturbances themselves" (Buber: 2002, p. 20). The current literature even uses medical language, for example, on the "onset, duration, and termination" of civil war (Hegre, 2004, pp. 243–252). Theories from international relations have been deployed to explain the Yugoslav conflicts as a security dilemma; state weakness has been found to be more important than ethnic differences; and micro-economic explanations have stressed the costs and benefits of participation in civil war. Together these constitute a 'structural turn' in theorizing (Kissane and Sitter, 2012).

The security dilemma provides an explanation of how a relatively stable society, like Yugoslavia, rapidly deteriorated into civil war without assuming that this process reflected prewar divisions (Posen, 1993, pp. 27–47). Anarchy is central. In the absence of central authority, the security requirements of one group are seen as a threat by another group. If the authority of the state collapses, two or more groups may come into conflict, not because they actively pursue this course of action, but because the measures they take to protect themselves constitute a threat to the other groups. Hence the suggestion that mutual fear caused the Bosnian Civil War (Woodward, 1999).

Most of the post-1945 civil wars have been produced in poor countries, by the increasing contradiction between new political and economic aspirations, often fed by the example of other countries, and the relatively oppressive governments with which people are confronted (Luard, 1972, p. 14). However Fearon and Laitin (2003) argue that this contradiction results in civil war mainly when the state is weak. Their statistical results find that low GDP makes civil war more likely, and they explain this in terms of the low capacity of 'financially and bureaucratically weak states.' Mountainous terrain and large populations make civil war more likely because they make state control more difficult. 'Grievance' factors such as ethnic diversity and the low level of democracy, do not affect civil war: they are seen as the product of civil wars, not their cause.

For Fearon and Laitin civil wars in failed states reflect *permanent* "conditions that favour insurgency – in particular state weakness marked by poverty, a large population and instability" (Fearon, 2004). Collier and Hoeffler add a stress on the costs and benefits to the actors in insurgencies. Greed is key, and is linked to the 'resource curse': rebels' quest for economic gain, notably in the shape of 'predation of the rents from primary commodity exports,' is the most important factor. 'Grievance,' defined as dissatisfaction caused by ethnic or religious differences, political repression or unequal economic distribution, is less important. Like Fearon and Laitin they find a strong statistical correlation between GDP and civil war, but their explanation lies in the actors' quest for private gains and the opportunities that civil war provides for this. As their subsequent study put it: 'where rebellion is feasible it will occur: motivation is indeterminate, being supplied by whatever agenda happens to be adopted by the fist social entrepreneur to occupy a viable niche' (Collier et al., 2009).

Instead of focusing on the 'triggering events' which lead to civil war, the latter two studies try to relate the variation in civil war to countries' longer term social, economic, and institutional features. Rather than going into detailed analysis of the various micro processes which cause civil war, such studies hang their analyses on the two tail ends of the causal chain; initial structural conditions on the one hand, and outcomes (violence or nonviolence) on the other. What connects these structural attributes to the onset of civil wars in these theories are (rationalist) stipulations (greed not grievance) regarding human motivations which are employed to substitute for the complex causal processes behind civil wars which this literature is unable or unwilling to specify (Ringmar, 1996, p. 36). In the words of one critic "homo economicus goes to war" (Cramer, 2006, pp. 124–139).

These studies combine a root cause approach to conflict, once prominent in sociology, with statistical methods. Yet root cause explanations require a clear hierarchy between variables, which is hard to establish. In Yugoslavia had the state remained intact, the spiral of violence would have been avoided. Yet the political salience of ethnic identity in the Balkans, was also a root cause. Causal hierarchy could be established through process-tracing and establishing which came first in the sequence of events. The problem is that these two factors were mutually constituted. Table 1 represents this mutual constitution.

What about the grievances the actors themselves articulate as the reason for conflict? Collier, Hoeffler, and Rohner (2009) develop a radical 'feasibility hypothesis,' which holds that where rebellion, driven by greed, is financially and militarily viable, it will occur (as policy entrepreneurs sooner or later step forward and formulate a suitable grievance). Others argue that there can be no clear rational course of action in the absence of interpretative filters. Work on Indonesia, Northern Ireland, and the Philippines suggests the prior existence of myths and memories was a necessary condition for the eruption of conflict over material resources and state power (Aspinall, 2007; Kaufmann, 2006). There is also philosophical difference. The realist premise of the first approach is that 'reality' – in the form of ethnic groups, material resources,

terrain – is something 'out there.' However, actors' perceptions are social facts too. We live in a material world which we interpret, and it is on the basis of these interpretations that we present various options to ourselves (Ringmar, 1996, p. 37). The option to engage in civil war is one such decision.

Ultimately, structural approaches can only investigate underlying factors which make societies prone to violence, but are weak when it comes to identifying catalytic factors (Brown, 1996). They should distinguish between the factors that bring a conflict into existence and those that make it intractable, since those factors identified by large N studies are usually of the latter kind. The age-old question of sociology – do structures really determine human action? – returns. Two countries with similar social structure may have very different experiences of conflict and a given society may experience phases of peace and of violent conflict despite the underlying fault lines remaining constant. These issues are acknowledged in Collier and Sambanis (2005a,b) series of cases studies, including the difficulty of identifying causal mechanisms with general models, and the question of why some political conflicts escalate into civil war while others do not.

The alternative (constructivist) approach focuses on relationships between actors. Interests and identities are not fixed by the material world, but emerge in an unpredictable way through processes of conflict and interaction. Moreover, perceptions can change during conflict, causing a shift in the underlying conditions of conflict that has significant consequences for its duration. For this reason process-based explanations are increasingly popular. Tilly (1973, p. 439) argued that theories that linked conflict to modernization for example, "fall wide of the mark," because they miss "the extent to which violence is a contingent outcome of interaction among contenders and governments." Tarrow's (2007, pp. 587–600) review of four studies identified a "(re)turn to case-study methods," and also concluded: 'it is not quantities but *interactions* that matter.' Increasing emphasis has been placed the way identities are formed during conflict.

Root cause approaches begin with a checklist of potentially relevant causal factors and then reorder them hierarchically for each case. Yet their importance varies over time. Process-based theories capture conflicts dynamics better. The Chechen struggle was essentially one of secession, but at different stages of the conflict it was viewed through different ideological frames. Hughes (2007) study shows that how an issue is reframed – from being about the desire for a territorial state to religious jihad – altered states' views about whether the Chechan issue was negotiable (ibid, 203. Thus a temporal perspective was required in order to know when a conflict was ripe for resolution. Moreover, identifying the causes of civil war is not the same as identifying the causes of its violence. Kalyvas' (2006) study of the Greek Civil War of the 1940s compares two villages in the plain of Argos, Manesi, and Gerbesi (now Midea), which were the same size, of a similar social outlook, and also shared a common descent and social structure. Egregious episodes of violence during the civil war (including of children and the elderly) took place in only one, in Gerbesi in August 1944. In the other, they were repelled by the villagers. The differences cannot be explained in terms of ideology, the claims of groups, or different economic structures.

Conclusion

If process-based approaches capture the dynamic nature of conflicts and their sensitivity to initial conditions, what remains of cause and effect? Processes are not necessarily causal: to say a situation produced a civil war because it polarized to that extent is tautological. Structures in contrast are 'emergent properties' which are the product of past actions giving them causal status in any society. The causal theories summarized here do not tell us enough about where these structures came from, who built and captured them, and for what purpose. Structures (including states) do not determine action, but set the parameters for action and carry meanings which inform the terms of any conflict about them. The relationship between state weakness and civil war must thus be affected by the meanings of structures for different groups. If their construction had meaning during decolonization; so too do their subsequent failures.

The civil war literature is marked by porous scholarly boundaries. The concept itself lacks conceptual autonomy and can legitimately be the province of international relations scholars. Many can only define civil war by contrasting it with other types of war. On the one hand, only science has the need to eliminate rival theories as a criterion of scholarly progress. Yet employing a single causal model for all the various types of internal war may actually obscure rather than illuminate the distinct causal factors at work in these types of conflict (Wood, 2003, p. 256). While the literature on revolution struggled to accommodate ideological factors (often specific to cases) in comparative analysis, that on civil war now tends to reduce identities and ideas to material motivations. Yet the state is a conceptual as well as material variable, the importance of which varies from society to society, so much that a loss of state capacity in one country will not have the same consequences as in another. A recent study of four internal wars in Latin America found no relationship between violence and attitudes to either state or nation (Centeno et al., 2013).

The field of civil war studies is new and interdisciplinary. Works of theoretical synthesis are badly needed. Ultimately, civil war should be regarded as a distinct form of internal war. Such conflicts can be internal in two ways; they take place within a political unit recognized as such by the international community, or in a society united by shared norms and values. Since levels of social integration, and of political development generally, are not constant, civil war studies have to say more about the political communities within which they take place. This is as important an ontological question as that of the contrast with other types of war. Throughout history such conflicts have polarized precisely because they put into doubt the basis of political communities. Whether this basis is institutional, economic, or cultural, we should accept that the foundations of social existence in our region will not be those of the rest of the world.

Abstract

The concept of civilization as it is recognizable today, emerged with the rise of historical consciousness in Europe in the eighteenth and nineteenth centuries, and achieved global spread in the twentieth century. Civilization came to constitute a primary unit of historical discourse, in association with cognate terms such as culture, quite apart from its indication of certain morphological features of human society, such as urbanism. Broadly conceived, the notion of civilization has served two schemas of world history, the one universalist and evolutionist and the other particularistic and vitalist. Both notions have ideological implications, and were often deployed in conflicts between universalist-progressivist and conservative-nationalist political creeds, the former laying emphasis on the normative and morphological continuities in human societies, while the latter stressing openness to historical becoming as well as societal and historical transformism. Quite apart from the normative implications of both notions, one valorizing abiding resources of particularist national and civilizational character and the other speaking for an open notion of progress, recent historical research has rendered possible the concrete and properly historical consideration of the notion of historical continuity beyond the boundaries of the ideological commitment of the two notions of civilization that have profoundly marked the categorization of historical material and historical periodization in general.

The concept of civilization is inextricably connected with the conditions of its emergence, most notably with the rise of historical consciousness in Europe in the eighteenth and nineteenth centuries, as well as the globalization of this form of historical understanding and correlative forms of intellectual practice. The concept is complex and imprecise in its definition, but ubiquitous in its uses, and inextricably imbricated with other categories by which historical materials are organized, such as culture, nation, and race. Apart from designating certain morphological features of human society, particularly with reference to urbanism and urbanity, civilization has been a schema for historical categorization and for the organization of historical materials. Here it has generally taken two forms, the universalist evolutionist, and the romantic particularist. The latter was tending to regain, in the ascendant context of identity politics, a certain hegemonic primacy worldwide at the close of the twentieth century. In all, the concept of civilization forms a crucial chapter in the conceptual, social, and political history of history; it, or its equivalents are presupposed, implicitly or explicitly, in the construal and writing of almost all histories.

Prehistory

The mental and social conditions for speaking about civilization in a manner recognizable in the year 2000 were not available before the middle of the eighteenth century. Hitherto, in Europe as elsewhere, large-scale and long-term historical phenomena, which later came to be designated as civilizations, had been categorized in a static manner that precluded the consciousness of directional or vectorial historicity as distinct from the mere register of vicarious change.

Hitherto, the succession of large-scale historical phenomena, such as Romanity or Islam, had been regarded (1) typologically, most specifically in the salvation-historical perspective of monotheistic religious discourse, in which successive events are taken for prefigurations and accomplishments of each other; (2) in terms of the regnal succession of world empires; and (3) in the genre of regnal succession, which started with the Babylonian king lists and the earliest stages of Chinese historical writing, and culminated in medieval Arabic historical writing. Not even the schema of state cycles evolved by the celebrated Ibn Khaldun (d. 1406), where civilization (*'umrân*) was quasisociologically identified with various organizational forms of human habitation and sociality, could meaningfully escape from this finite repertoire of possible historical conceptions.

In the perspective of typology, the continuity of historical phenomena was expressed in the repetition of prophecies successively reaffirming divine intent and inaugurating a final form of order whose *telos* would be the end of time. Thus the Jewish prophets repeat each other and are all figures for Abraham; Jesus is at once the repetition and termination of this unique cycle of terrestrial time and is prefigured in Jewish prophecies. Muhammad is the final accomplishment and the consummation of earlier prophetic revelations, prefigured in Jewish and Christian scriptures; his era inaugurates the consummation of time with the Apocalypse. The structure of time in the Talmud, in the Christian writings of Eusebius (d. 339), of Augustine's Spanish pupil Orosius (fl. 418), of Bernard de Clairvaux (1153), as in Muslim writings such as Muhammad's biography by Ibn Ishâq (d. after 761), or the universal histories of Tabarî (d. 923) and Ibn Kathîr (d. 1373) is homologous.

All but Jewish typology is independent of ethnic origin or geographical location, and construes historically significant units as religious communities of ecumenical description. This yields the second mode of organizing historical phenomena, the regnal. Thus, the regnal categorization of long-term historical phenomena of broad extent was expressed in terms of the succession of four ecumenical world empires, succeeding one another as the central actors in world history: the

Assyrio-Babylonian, the Median-Persian, the Alexandrian-Macedonian, and the Roman. This perspective was shared by the *Book of Daniel* and by ecclesiastical works, especially Syrian and Byzantine apocalypses influenced by it, albeit with minor variations, as in Orosius' substitution of the Carthaginian world empire for the Median-Persian. Muslim caliphs considered their own ecumenical world empire to be the fifth and final order of world history, a conception shared by Muslim apocalypticism and, with many complications and nuances, by universal histories written in Arabic, all of which regarded dynastic succession as both prophetic inheritance and as the renewal of ecumenical imperial ambition, transferred from one line to another.

Analogously, medieval Christian polities, Byzantine as well as Frankish, subscribed to the same theory of *translatio imperii* by regarding themselves as being in a direct line of typological continuity with Rome, variously through Byzantium, the 'New Rome,' or the Holy Roman Empire. In both, Romanity was the worldly cement of Christianity. This was a conception developed by Eusebius for his contemporary overlord Constantine, and was to remain effective until the dawn of modern times. In all cases, the past was understood to have been completed at its inception, with subsequent polities reenacting the foundational event.

Finally, mention must be made of the disjunction between these metahistorical and transcendental realms of typological continuity, and the all-too-human chaos of particular histories. No movement or qualitative change is discernible in the context of these, only the predictable succession of wars, rapine, pestilence, and occasionally of praiseworthy acts, without connection with an order of reality that might transcend the events themselves and render sense unto them.

Two roughly contemporary events heralded a new conception of history that made the modern notion of civilization conceivable. Both were specifically European, but their conceptual consequences were globalized in the course of the nineteenth and twentieth centuries. The first was Humanism, particularly in Italy, which for the first time broke the spell of Roman continuity by construing the immediate past as an age of darkness, and by confining Roman grandeur to the republican and early imperial ages. Thus Petrarch's (d. 1374) project of classicism counterposed to living tradition; Flavio Biondo's (d. 1463) anticipation of division of history into the classical, the medieval, and the modern; and Lorenzo Valla's (d. 1457) refutation of medieval documentary forgeries such as the *Donation Constantini*, based on an argument from anachronism: together, these laid the ground for a view of history as the domain of change rather than of repetition.

Needless to say, the notion of *translatio imperii* was no longer tenable in this context. It is at this point that Humanism converged with the other event foundational of the modern historical consciousness, namely, the Reformation. Criticism of the Church by Wycliff (d. 1384) and Luther, and the historiographic expression of this antitraditionalist fundamentalism in John Foxe's *Acts and Monuments* (1563), were in crucial ways congruent in their conception of the past with Humanism. The identification of the Pope with the Antichrist, the designation of the greater part of the history of Christianity as a history of falsehood, and the devalorization of the immediate past as abiding tradition and its construal as degeneration, also led to the rejection of the notion of *translatio imperii*, and the substitution of notions of Reformation and renovation to that of transfer in continuity.

Thus the ground was prepared for notions of rise, decline, and fall – most notably the decline and fall of Rome and the reclamation of Roman republicanist models in a spirit of revivalism – that were finally to mature in the eighteenth century, with Gibbon and Montesquieu among others, spurred along with the development and ultimately, in the late eighteenth and during the nineteenth centuries, the institutional transformation of philology and antiquarianism into history as a topic of research detached from rhetoric. This was far beyond the late flowering of medievalizing typology with Bossuet (d. 1704), and it made the past tangible in its having been (*Vergangenheit*), most graphically represented in the establishment of museums during the eighteenth century in many European capital cities.

With Voltaire and other eighteenth-century figures like Volney and Chardin, another notion crucial for speaking of civilization was developed. The notion of qualitative societal and cultural difference (*les moeurs*) – quite apart from the dynastic and the religious – was now available in the eighteenth century, as Europe was accounting for her differences from the Ottomans, the Persians, the Chinese, and tribal peoples in the Americas.

Whereas previously the notion of historical senescence may have been used in a tragical and rhetorical sense, the new notion of decadence required the correlative notion of progress and amelioration. These notions are the very conditions of possibility for conceiving of civilization as the accomplishment of a continuous line of historical development in which origins and beginnings are transcended rather than repeated.

Word and Concept

The terms civilization and culture are intimately related in their reference, and in many instances are used almost interchangeably, according to national and linguistic conventions. Both are terms of ancient vintage, which underwent a gradual lexical expansion until, in the eighteenth century, they came to designate meanings that are recognizable in 2001.

In the course of the seventeenth and eighteenth centuries, the meaning of the term culture expanded, in English, French, and German (as *Kultur*) from a medieval sense indicating the cultivation of land and of the religious cult, figuratively to denote the maintenance and cultivation of arts and letters. This figurative sense was further extended in the course of the eighteenth century to encompass the nonmaterial life of human societies in a very broad sense encompassing the refinement of manners no less than intellectual and artistic accomplishments associated with the Enlightenment – the former sense still persists in terms such as *haute couture* and *Kulturbeutel* (vanity case).

The term was used both locally and in contrast to societies adjudged still living in a state of nature, although in German the accent had been on an esthetic of the lofty and the sublime as distinct from the crassly material, in association with a correlative emphasis on cultivation, *Bildung*, both individual and collective. In this way, the term was opened up to

impregnation by the emergent notion of progress, the progress of individual societies as of humanity in general regarded both as a process natural to human society and as a principle of normative ranking among societies.

Not dissimilarly, and in imitation of 'culture,' in the eighteenth century the term civilization underwent – especially in France and somewhat later in England – a figurative expansion in its lexical reference from the Latin *civilis*, life under reputable forms of government, to the broader designation of order, civil, and governmental. This order befitted developed societies that might regard themselves as civilized in contradistinction to other, barbarian or savage, yet-to-be-civilized societies. The contrastive connotations of 'civilization' were far more accentuated than those of 'culture,' which was more commonly used in Germany, a land then with little or no experience of the world outside Europe. 'Culture' also came to be used in France and more saliently in England, as in Germany, decidedly to signal social distance and social distinctions within particular countries.

In all cases, these two terms increasingly came to be associated with a developmental perspective on history: not only the linear and cumulative course traversed by historical phenomena in time but also of languages, geological layers, plant and animal species, and human societies generally (and later, races), toward greater differentiation, complexity, and accomplishment. Correlatively, the meanings conveyed by these terms were implied by other terms or by none at all, as, for example, with Rousseau and Voltaire.

The nineteenth century witnessed a complicated relationship between 'culture' and 'civilization' whose fields of connotation and denotation shade into each other in a manner that has not helped the distinctive clarity and definition of either. The crucial player here was Germany, where *Kultur* took a decidedly romantic-nationalist turn in the early nineteenth century, dwelling on national uniqueness and individuality, and buttressed by the emergence of *Kulturwissenschaft* as a discipline and by studies of folklore.

The further developments of this politicocultural impulse toward the end of the nineteenth century led not only to the profuse discourses on decadence, *Entartung*, ('disnaturation') but also to the extension to France of this particularitic understanding of culture – and of civilization – under the influence of de Joseph de Maistre and the Catholic Counter-Enlightenment. As a result of Franco-German conflicts and of the severe stresses within France, a battle was waged between the advocates of 'culture,' upholders of national particularism, and of 'civilization,' champions of Enlightenment universalism accused by their detractors of crass materialism, a battle that reached its apogee during the First World War in the polemics between Romain Rolland and Thomas Mann.

Yet 'civilization' itself had been increasingly more receptive to particularism and nationalism, most specifically in historical writing. Books on the civilization of France, Germany, Europe, Italy, and England, emerged from the second quarter of the nineteenth century, and in certain ways, the very currency of the term made it open to divergent uses. Toward the end of that century, the term came to be used under the influence of the German notion of *Kultur*, a term often rendered as 'civilization' in French translations of German works. One additional but decisive factor was English anthropology, with the appearance in 1871 of Edward Tylor's *Primitive Culture* (1958), and the subsequent predominance of the term 'culture' to designate a condition, on a ladder leading from savagery to barbarism and finally to civilization, in Anglo-Saxon anthropology. With the discovery and mystique of classical Greece toward the end of the eighteenth century, of the unity of the 'West' from Greece, through Rome, on to the Romano-Germanic peoples in the Middle Ages, culminating in modern European civilization, was to become the *locus classicus* of this notion of civilization.

In the later part of the nineteenth century and throughout the twentieth century, both the terms and conceptions outlined were subsequently taken over and became crucial instruments of historical categorization in India, China, and the Arab countries and elsewhere. In Arabic, *thaqafa*, an equivalent to the German *Bildung*, came to stand for culture, normally taken to designate intellectual and artistic life in a manner strongly elitist in character, and *hadara* was used for civilization, taken as a more general concept indicating the entire life of society including material life.

Continuities: Relativism

Linear developmentalism had, in general, underlain the entire body of diverse discourses on civilization and of its sister concept of culture. This developmentalism bifurcated along lines that may be characterized broadly as German and French in original inspiration.

Of the two, the former had been more intimately associated with romantic national and, the latter, with civilizational particularism, producing a natural history of human groups regarded in analogy to organic species. These human groups were thus conceived of as self-subsistent, continuous over time, largely impermeable, essentially intransitive, and according to many representatives of this view, almost congenitally given to conflict and war.

Originating in conservative reactions to the Enlightenment, with a strong anti-Gallic political impulse, this theory of historical and social development was associated with figures such as Johann Gottfried Herder in Germany and Edmund Burke in England, although it did have a strong representation in France among royalist, Catholic, and other antirevolutionary (1789, 1848, 1871) currents represented by figures such as de Maistre, Gobineau, and Gustave Le Bon. The principal conceptual feature of this antimechanistic concept of history was insistence on individuality in the histories of different nations, races, and civilizations – terms often conflated in various combinations, in analogy with biological organisms, and perhaps best captured in the capacious semantic field of the German word *Volk*. In this sense, one may speak of continuity with pre-Enlightenment concepts of a social organism modeled upon the integrated somatic unity of the human body, as had been previously thought in medieval Arabic historicopolitical writings and in medieval European conceptions from the time of John of Salisbury (d. 1180). The fear of decline and decadence, conceived as a breakdown of a natural order, was the specific point at which continuity with medieval organismic concepts of the historicopolitical order made itself evident and conceptually formative. This was at a time when the idea of progress – and in contrast to it – had become a genuinely historical category, involving a consequential

conception of change, of evolutionism, of the temporality specific to events (*Verzeitlichung*), and of a distanciation correct between human and natural histories.

The course of a particular history was seen to reside in a number of essential features, which Herder termed *Kräfte*, resulting in a history which, increasingly elevated and evolutive in the course of time as it may be, was still governed by principles that were, in essence, changeless, principles that imparted individuality upon these intransitive histories.

Whereas the Enlightenment provided, and the nineteenth century elaborated, a notion of genetic development along an axis of cumulative time to which civilizations and other historical masses are subject, the organismic, particularist notion conceived of a civilization as bound to a self-enclosure inherent in its origins. Although this did not necessarily lead to a historical cyclism, it constituted its conceptual condition of possibility, and facilitated culturalist notions of nationalism that spoke in terms of 'revival.'

It was a cyclical notion of the history of cultural and civilizational circles, *Kulturkreise*, according to Ernst Troeltsch (1920) that was made conceivable by the manifold discourses on decadence, malfunction, and historical pathology, notions that implicitly involve a measure against a more consummate state of organic health and well-being implicit in the foundations of each. It was the systematic elaboration of the decadence/normalcy structure that led to great schemas of world history, divided into intransitive civilizations, of Oswald Spengler's *Untergang des Abendlandes* (Spengler, 1922) and of the Spenglerian heresy represented by Arnold Toynbee's *A Study of History* (Toynbee, 1934–1959).

Described by Claude Chaunu (1984 as 'a samsara of historical forms,' these vitalist theories of the rise and inevitable decline of civilizations constitute a naturalistic morphology of historical becoming. From this perspective, civilizations were seen as historical phenomena that are perpetually in conflict with one another, each endowed with a particular ethos or animating principle. Such were Spengler's (1922) Magian culture (the Perso-Islamic) and Promethean culture (the European). Such were also Toynbee's (1934–1959) Syriac and other civilizations, although with this latter author the inner definition of civilizations was less clearly predetermined, and founded on a firmer and far more scrupulous empirical foundation than with Spengler. Nevertheless, Toynbee does characterize civilizations in terms of particularistic impulses, such as the estheticism of Greek civilization, the religious spirit of the Indian, and the mechanistic ethos of the West. Each of these is an integrated pattern of daily life, on attitude toward the holy, a style of jurisprudence, a manner of government, an artistic style, and much more.

With both authors, the historical phenomena, respectively, designated as 'cultures' and 'societies,' obey an iron law of rise and decline, of glory and senescent atrophy, the terminal phases of which Spengler, in keeping with German usage of the day, derisively termed 'civilization.' It is noteworthy that this morphology of historical masses, be they called civilizations, cultures, or societies, that this monocausal description in terms of basic traits such as the Promethean or the esthetic, was congruent with certain developments in anthropology, particularly in American anthropology in the first half of the twentieth century (Franz Boas, Alfred Kroeber, Ruth Benedict, and Edward Sapir), which identified separate societies according to self-consistent and intransitive personality profiles that they ostensibly gave rise to. This had a decisive influence on the introduction of organismic thinking into the human sciences in general. After a long period of disrepute, the 'culturalized' notions of human collectivities, of self-enclosure, and of continuity have come back to center stage at the close of the twentieth century, correlatively with the politics of identity worldwide.

The organismic and vitalist notion of civilization was, and still is, extremely effective in the writing of history and in the late twentieth century has had a certain political salience in terms of Samuel Huntington's 'war of civilizations' and the mirror-image riposte in terms of the 'dialogue of civilizations.' It denies the possibility of a general human history, which it regards, in the words of Ernst Troeltsch (1920), as being 'violently monistic,' and construes the task of a history of civilizations as separate histories of Europe, China, India, Islam, Byzantium, Russia, Latin, and Protestant Europe, and others, in various possible permutations and successions, as separate cultural and moral spheres that are merely contiguous in space. Correlatively, this constituted the conceptual armature of certain forms of violently particularistic history that was mirrored or endogenously paralleled, among others in India, for instance (Savarkar, 1969), or in the writings of radical Muslim ideologues.

Novelties: Universalism

The deficit in historicity evident in romantic and vitalist historism, with its emphasis on organic continuity, was to a great extent made up in the more consistently evolutionist accounts of historicism. It was this conception of history, at once evaluative, evolutive, and vectorial, which bore the burden of the universalist notion of civilization. Whereas in historism the bearers of civilization – or rather of 'culture' – were particular peoples or individual historical itineraries, such as the West or Islam, the whole of humanity partook of the development of civilization, which, in the historicist perspective, was universal and continuous.

Several versions of this were in evidence, of which two are of particular note due to their wide conceptual incidence and the social and political influence they exercised through worldwide social movements, both revolutionary and gradualist, inspired by the Enlightenment. According to this conception of a universal civilization, human societies pass through a uniform series of progressive developments, which result in intellectual and moral elevation. They also result in superior social, economic, and political levels of development, marked by a higher and wider order of rationality, social differentiation, and control over nature whose instrument is science.

The more consistently universalist of these versions – exemplified, among others, by Jean Marquis de Condorcet, Auguste Comte, and Herbert Spencer, and in the evolutionist anthropology of Tylor (1958) – saw the whole of humanity as being predisposed to this upward movement. Nevertheless, according to this view some peoples may still subsist in a condition that others (Europe) had already surpassed, being still captive to superstition, to a weak organization of society and the economy, and to undeveloped political institutes

(despotism, as in the case of Orientals, or otherwise various forms of acephalic organization, as is the case with primitive societies). The only caveat here is that many theorists of the evolution of human societies did not see human improvement as uniform in developed societies themselves, but that developed societies were not only internally differentiated in the levels of accomplishment attained by different social groups, but also liable to fall far below the moral ideals that development makes possible. Nevertheless, much writing on the history of universal civilization, especially in countries influenced by Marxism, such as the Soviet Union or the People's Republic of China, saw the historical itineraries they led as crucial and exemplary steps in the development of humanity at large. In this way, the histories of Russia and China come to recuperate and tap world history at large by acting as the vanguard and exemplar of its future consummation.

Correlatively, the other conception of universalism, and this is one of profound conceptual and political importance, recognized the past contributions of various civilizations – the Mesopotamian, Egyptian, and Islamic, and in some instances the Indian and the Chinese as well – to the course of human civilization, which eventually lodged itself in Europe, defined as the abode of Romano-Germanic history, or even in small parts of Europe, such as France or Prussia. This writing of universal history, much in evidence in the plethoric literature of universal histories both popular and learned, was expressed in what is perhaps its most accomplished general formulation by Georg Hegel (1956) in the nineteenth century, and by Karl Jaspers (1949) in the twentieth – the latter is little read today, but he is the one who, nevertheless, captures this notion with special clarity.

Not infrequently, this second type of universalist history is allied to an important element derived from the romantic theory of the history of civilizations treated in Section Novelties: Universalism, namely, the presumption of very long-term individual continuity. Thus the point is habitually made, with varying shades of emphasis and nuance, that universal civilization made Europe its eventual home because of some abiding characteristics possessed *ab initio* by 'the West,' such as rationality, the spirit of freedom, vigor, and dynamism. This changeless West is counterposed to an eternal East, such as Mesopotamia, Egypt, and Islam, which, their relative erstwhile merits apart, constitute, in a categorical degradation, a mere prehistory to fully developed civilization. East and West – not to speak of Islam, the name of a religion transmuted into an atopic location – are metageographical notions that do not allow, except with anachronistic violence, for projection into the antique and late antique worlds. However, this does not disturb the ideological coherence of this notion of civilization.

Beyond Totality

Writing about civilization according to the manners outlined contained both large-scale abstraction and a great deal of precise empirical historiography. Under the influence of Marxism, acknowledged as such as well as implicit, historical scholarship, and most specifically social and economic history in the traditions of Max Weber and of the Annales school, produced specifications regarding material and other aspects of civilization that allayed, to a considerable degree, the rhetorical force of thinking civilizations in terms of purely moral and ideological continuities, betokening exclusive sociohistorical groups. The notion of a Judeo-Christian civilization, as distinct from textual typology within the Bible, is an excellent illustration of this, having been born and expanded in specific circumstances following the Second World War.

In this way, civilizations for contemporary historical writing have come to comprise the total historical conditions that exist in a specific place and time: functional and organizational forms of the state; the *longue durée* of demographic, agricultural, economic, social, urban, ecological, climatic, and other forces underwritten by geographical structures and relations; and nonmaterial culture, such as arts, letters, cognitive structures, and religions. The possibilities of a total history of a civilization is, it must be stressed, an expansion of a previous and more limited form of the cultural history of a particular epoch, exemplified by Jakob Burckhardt's studies of Constantine and Renaissance Italy (Burckhardt, 1955: Vols. 1 and 3).

As a result, since about 1950 it has become possible historically to specify the material elements that constitute the history of a civilization; however, its temporal and geographical boundaries may be defined. Correlatively, it has become possible to conceive of the specific differences between histories – China and Europe for instance, as in the work of Jacques Gernet (1988) – beyond a discourse on immobility and other immanent characteristics ascribed to this history or that, and to think of specificity in proper historical terms, such as the relative weight of various elements of the rural economy, the relation between state and the economy, the impact of metallurgy, and much more.

In this context, civilizational continuities came to be reconsidered in terms of historically determinant factors of a predominantly geographical nature, not so much in the spirit of geographical determinism as described by the German school of Friedrich Ratzel (1895), but with a greater degree of temporal specification, mediated by Lucien Febvre's (1925) consideration of historical geography and culminating in Fernand Braudel's study of the Mediterranean (1972–73). By the same token, it has become possible squarely to face the nominalist caution required in thinking about civilizations, and to think of their constitution, specification, and collapse in terms of the concrete historical investigation of demography, economy, and society without recourse to the metaphysical rhetoric of decline (Tainter, 1988).

These specifications apart, it remains true that the construal of civilizational intransitivity, with Braudel as with others, still needs to resort to a new redaction of the rhetoric of permanence, most particularly with regard to nonmaterial culture, now underscored and almost overdetermined by considerations of relief, soil, water supply, and means of transport – all of which are undeniable factors, albeit ones that modern technology and economy, most poignantly the postmodern economy, have rendered questionable.

Nevertheless, recent historical research has made it concretely possible to tap the genial formulations made by Marcel Mauss in 1930 (Febvre et al., 1930) concerning the categorization of historical masses: of civilizations as a 'hypersocial systems of social systems,' as transsocietal and extranational units of historical perception and categorization. These

are conceived of in opposition to specific social phenomena, and this conception of civilization valorizes the distinction between civilization, society, and culture, freeing the first of the deterministic and totalizing rhetorical glosses of metahistory, and making possible a veritable history of civilizations. Civilization may thus be considered as at once a particular instance of historical becoming, and a specific ideological redaction of the past whose relation to historical reality can be questioned and rendered historical. In this context, the historian may also be able to valorize the extremely expansive *longue durée* implied by such theories as Dumézil's (1958) Indo-European tri-functionalism without recourse to organismic and totalizing figures of particularity and continuity (Le Goff, 1965). A historian may be similarly able to valorize recent studies that stress the occurrence and communicability of recurrent phenomena of the imaginary order across vast spaces, cultures, histories, and times, as instanced by Carlo Ginzburg's study of the European witch hunts (Ginzburg, 1990). Finally, given the accent on complexity, one might be able to take the precise and nuanced study of levels and modes of socio-economic, political, institutional, ideational, and other instances of complexity – rather than criteria of simple continuity – as crucial to the delimitation of historical phenomena that one designates as 'civilizations.'

Abstract

The central analytical core of the term civilization as employed here is the combination of ontological or cosmological visions, of visions of transmundane and mundane reality, with the definition, construction, and regulation of the major arenas of social life and interaction. The full development of the distinct ideological and institutional dimensions, and of some awareness of their distinctiveness, has emerged in some very specific historical settings – namely, the so-called Axial Civilizations. The crystallization of these civilizations constitutes a series of some of the greatest revolutionary breakthroughs in human history, which have shaped contours of human history in the last two to three millennia. The central aspect of these breakthroughs was the emergence and institutionalization of new ontological metaphysical conceptions of a chasm between the transcendental and mundane orders.

Introduction

The term 'civilization' has been used in modern social science and historical literature in several different ways. One such way, developed above all in Germany from about the end of the nineteenth century through the period up to World War II and perhaps best represented by scholars like Alfred Weber (and taken over to a certain extent in the English-speaking world by R. M. Mclver), designated 'civilization' – as distinct from 'society' and above all from 'culture' – as encompassing above all the technological, material factors and to some extent organizational aspects of social life as against the deeper, more 'spiritual' cultural and aesthetic ones.

Another designation of the term, made famous by Norbert Elias in his *Über den Prozess der Zivilisation* (1939) focused on the 'socializing' process through which the image of the civilized person, as constructed in the courtly and also early bourgeois society in Europe, was promulgated and institutionalized. This designation of civilization was related to an earlier one rooted in the French Enlightenment, in which civilization was seen as the opposite of barbarism. However, in later works by Elias's followers, for instance Goudsblom, this view of civilization was extended to cover many other societies and historical periods, going back even to the impact of the presumably first domestication of fire.

The third and most extensive designation of civilization was promulgated by scholars such as Max Weber, Emile Durkheim, Oswald Spengler, Pitirim Sorokin, Arnold Toynbee, A.L. Kroeber, Carroll Quigley, Cristopher Dawson, Fernand Braudel, William H. McNeill, Adda Bozeman, or Immanuel Wallerstein, and lately very forcefully by Samuel Huntington. However great the differences in perspective, methodology, focus, and concepts that pervade the works of these scholars, they share the use of the term civilizations as distinct societal-cultural units which share some very important, above all cultural, characteristics. Here we shall use the term civilization in a way very close to, but also distinct from, such a designation.

> Civilization as combination of ontological or cosmological visions, of conceptions of trans-mundane and mundane reality, with the definition, construction, and regulation of the major arenas of social life and interaction

The central analytical core of the term civilization as employed here – as distinct from such social formations as political regimes, different forms of political economy or collectivities like 'tribes,' ethnic groups or nations, and from religion or cultural traditions – is the combination of ontological or cosmological visions, of visions of trans-mundane and mundane reality, with the definition, construction, and regulation of the major arenas of social life and interaction.

The central core of civilizations is the symbolic and institutional inter-relation between the formulation, promulgation, articulation, and continuous reinter-pretation of the basic ontological visions prevalent in a society, its basic ideological premises and core symbols on the one hand, and the definition and regulation of major arenas of institutional life on the other. Such definitions and regulations construct the broad contours, boundaries, and meanings of the major institutional formations and their legitimization, and greatly influence their organization and dynamics.

The impact of such ontological visions and premises on institutional formation is effected through the processes of interaction and control that develop in a society. Such processes of control – and the opposition to them – are not limited to the exercise of power in the 'narrow' political sense. Rather, they are activated by major elites in a society. The most important such elite groups are the political, the cultural, and the economic ones and those which construct the solidarity and collective images of the major groups, all of which have different cultural visions and represent different interests.

The structure of such elite groups is closely related, on the one hand, to the basic cultural orientations prevalent in a society; that is, different types of elite groups bear different orientations or visions. On the other hand, and in connection with the types of cultural orientations and their respective transformation into basic premises of the social order, these elite groups tend to exercise different modes of control over the allocation of basic resources.

Such combination of ontological visions and of structuration of institutional formations and collective identities constitutes an inherent component of the formation of any society, and is always closely interwoven with the more

organizational aspect of any institutional formation – political, economic, or family and kinship.

The very implementation or institutionalization of such premises and the concomitant formation of institutional patterns through processes of control, symbolic and organizational alike, also generate tendencies to conflict and change. The crystallization of these potentialities of change usually takes place through the activities of secondary elite groups who attempt to mobilize various groups and resources to change aspects of the social order.

The full development of the distinct ideological and institutional dimensions, and of some awareness of their distinctiveness, has emerged in some very specific historical settings – namely, the so-called Axial Civilizations – even if some very important kernels thereof can be identified in some archaic civilizations such as those of ancient Egypt, Assyria, or Mesoamerica.

Axial Age Civilizations: the Reconstruction of the World and the Crystallization of Distinct Civilizational Complexes

By Axial Age civilizations (to use Karl Jaspers' nomenclature), we mean those civilizations that crystallized during the thousand years from 500 BC to the first century of the Christian era, within which new types of ontological visions, of conceptions of a basic tension between the transcendental and mundane orders, emerged and were institutionalized in many parts of the world. Examples of this include ancient Israel; later in Second-Commonwealth Judaism and Christianity; Ancient Greece; possibly Zoroastrianism in Iran; early imperial China; Hinduism and Buddhism; and, beyond the Axial Age proper, Islam.

The crystallization of these civilizations constitutes a series of some of the greatest revolutionary breakthroughs in human history, which have shaped contours of human history in the last two to three millennia. The central aspect of these breakthroughs was the emergence and institutionalization of new ontological metaphysical conceptions of a chasm between the transcendental and mundane orders.

The development and institutionalization of these ontological conceptions entailed the perception of the given mundane order as incomplete, inferior – oftentimes as evil and polluted. It gave rise in all these civilizations to attempts to reconstruct the mundane world, from the human personality to the sociopolitical and economic order, according to the appropriate 'higher' transcendental vision.

The revolutionary conceptions, which first developed among small groups of autonomous, relatively unattached 'intellectuals' (a new social element at the time), were ultimately transformed into the basic 'hegemonic' premises of their respective civilizations, and were subsequently institutionalized. That is, they became the predominant orientations of both the ruling elites and of many secondary elites, fully embodied in the centers or subcenters of their respective societies.

One of the most important manifestations of such attempts in all these civilizations was the strong tendency to construct societal centers to serve as the major autonomous and symbolically distinct embodiments of respective ontological visions, as the major loci of the charismatic dimension of human existence. But at the same time the 'givenness' of the centers could not necessarily be taken for granted. The construction and characteristics of the center tended to become central issues under the gaze of the increasing reflexivity which focused above all on the relations between the transcendental and mundane orders. The political dimension of such reflexivity was rooted in the transformed conceptions of the political arena and of the accountability of rulers. The political order as one of the central loci of the mundane order had to be restructured according to the precepts of the transcendental visions. The rulers were usually held responsible for organizing the political order according to such precepts.

At the same time the nature of rulers became greatly transformed. The king-god, embodiment of the cosmic and earthly order alike, disappeared, and a secular even if often semisacral ruler appeared. Thus there emerged the conception of the accountability of rulers and community to a higher authority, God, Divine Law, or a metaphysical vision. Accordingly, the possibility of calling a ruler to judgement appeared. One such dramatic appearance of this conception occurred in ancient Israel, in the priestly and prophetic pronunciations. 'Secular' conceptions of such accountability to the community and its laws appeared in both the northern shores of the eastern Mediterranean, in ancient Greece, as well as in the Chinese conception of the Mandate of Heaven.

Concomitantly with the emergence of these conceptions of accountability of rulers, autonomous spheres of law began to develop as somewhat distinct from purely customary law. Such developments could also entail some beginnings of a conception of rights even if the scope of these spheres of law and rights varied greatly. Of special importance from the point of view of our analysis is the fact that one of the most important manifestations of the attempts to reconstruct the social order was the strong tendency to define certain collectivities and institutional arenas as most appropriate for the implementation of transcendental visions.

Autonomous Elites as Bearers of Civilizational Visions: Change, Protest, and Heterodoxies

The development of new ontological metaphysical conceptions in the Axial civilization was closely connected with the emergence of a new type of elite, carriers of models of cultural and social order. These were often autonomous intellectuals, such as the ancient Israelite prophets and priests, and later on the Jewish sages, the Greek philosophers and sophists, the Chinese literati, the Hindu Brahmins, the Buddhist Sangha, the Islamic Ulema. Initial small nuclei of such groups of cultural elites developed the new ontologies, the new transcendental visions and conceptions, and were of crucial importance in the construction of the new 'civilizational' collectivities.

The new type of elites differed greatly from the ritual, magical, and sacral specialists in the pre-Axial Age civilizations. They were recruited and legitimized according to autonomous criteria, and were organized in settings distinct from those of the basic ascriptive political units of the society. The acquired a potentially countrywide and also trans-country status of their own. They also tended to become potentially independent of other categories of elites, social groups, and sectors.

At the same time a far-reaching transformation of other elites, such as political elites, took place. All these elites saw themselves not only as performing specific technical activities – be they those of scribes, ritual specialists, and the like – but also as potentially autonomous carriers of a distinct order related to the prevalent transcendental vision. They saw themselves as the autonomous articulators of the new order, and rival elites as both accountable to them and as essentially inferior. Moreover, each of these groups of elites was not homogeneous, and within each of them a multiplicity of secondary influentials developed.

These new groups became transformed into relatively autonomous partners in the major ruling coalitions. They also constituted the most active elements in the movements of protest and processes of change that developed in these societies and which evinced some very distinct characteristics at both symbolic and organizational levels.

First, there was a growing symbolic articulation and ideologization of the perennial themes of protest found in any human society, such as rebellion against the constraints of division of labor, authority, and hierarchy, and of the structuring of time dimension, the quest for solidarity and equality, and for overcoming human mortality.

Second, utopian orientations were incorporated into the rituals of rebellion and the double image of society. It was this incorporation that generated alternative conceptions of social order and new ways of bridging the distance between the existing and the 'true' resolution of the transcendental tension.

Third, new types of protest movements appeared. The most important were intellectual heterodoxies, sects, or movements which upheld the different conceptions of the resolution of the tension between the transcendental and the mundane order, and of the proper way to institutionalize such concepts. Since then, continuous confrontation between orthodoxy on the one hand, and schism and heterodoxy on the other, has been a crucial component in the history of mankind.

Fourth, and closely related to the former, was the possibility of the development of autonomous political movements and ideologies usually oriented against an existing political but possibly also religious center.

All these developments ushered into the arena of human history the possibility of the conscious ordering of society, and also the continuous tension that this possibility generated. The new dynamics of civilization transformed group conflicts into potential class and ideological conflicts, cult conflicts into struggles between the orthodox and the heterodox. Conflicts between tribes and societies could become missionary crusades. The zeal for reorganization informed by each civilization's transcendental vision made the entire world at least potentially subject to cultural- political reconstruction.

The Expansion of Axial Civilizations

Concomitantly with the institutionalization of Axial civilizations, a new type of intersocietal and intercivilizational world history emerged. To be sure, political and economic interconnection have existed between societies throughout human history. Some conceptions of a universal kingdom emerged in many post-Axial civilizations, like that of Genghis Khan, and many cultural interconnections developed between them, but only with the institutionalization of Axial civilizations did a more distinctive ideological and reflexive mode of expansion develop, with potentially strong semimissionary orientations.

It was indeed in close connection with the Axial civilizations' tendency to expansion that there developed new 'civilizational' collectivities, distinct from political and from 'primordial' ones, yet impinging on them, continuously challenging them, and provoking continual reconstruction of their respective collective identities. Such processes were effected by the interaction between the new autonomous cultural elites and the various carriers of solidarity and political elites of the different continually reconstructed 'local' and political communities.

In the continuous encounter of Axial civilizations with non-Axial or pre-Axial civilizations it was usually the Axial that came out victorious, without however necessarily obliterating many of the symbolic and institutional features of the non-Axial. The most important case of an encounter of non-Axial with Axial civilization in which the former absorbed the latter has been Japan.

The Multiplicity of Axial Civilizations and World Histories

The general tendency to reconstruct the world and to expand was common to all the post-Axial age civilizations. But the concrete implementation varied greatly. There emerged a multiplicity of different, divergent, yet mutually impinging world civilizations, each attempting to reconstruct the world in its own mode, and either to absorb the others or to segregate itself from them.

Two sets of conditions were of special importance in shaping these different modes of institutional creativity and expansion. One such set are variations in the basic cultural orientations. The other is the concrete structure of the social arenas in which these institutional tendencies can be played out.

Among the different cultural orientations the most important have been differences in the very definition of the tension between the transcendental and mundane orders and the modes of resolving this tension. There is the distinction between the definition of this tension in relatively secular terms (as in Confucianism and classical Chinese belief systems and, in a somewhat different way, in the Greek and Roman worlds) and those cases in which the tension was conceived in terms of a religious hiatus (as in the great monotheistic religions and Hinduism and Buddhism).

A second distinction is that between the monotheistic religions in which there was a concept of God standing outside the Universe and potentially guiding it, and those systems, like Hinduism and Buddhism, in which the transcendental, cosmic system was conceived in impersonal, almost metaphysical terms, and in a state of continuous existential tension with the mundane system. The 'secular' conception of this tension was connected, as in China and to some degree in the ancient world, with an almost wholly this-worldly conception of salvation.

A third major distinction refers to the focus of the resolution of the transcendental tensions. Here the contrast is between purely this-worldly, purely other-worldly, and mixed this-and other-worldly conceptions of salvation. The metaphysical nondeistic conception of this tension, as in Hinduism and

Buddhism, tends towards an other-worldly conception of salvation, while the great monotheistic religions emphasize different combinations of this-and otherworldly conceptions of the transcendental vision.

Another set of cultural orientations which influenced the expansion of the various Axial civilizations was the extent to which the access to their centers and major attributes of the sacred within them was open to all members of the community or was mediated by specific institutions.

In addition, there are differences in the way in which relations between the attributes of cosmic and social order of civilizational collectivities and those of the major primordial ascriptive collectivities are conceived – the extent to which there is a disjunction between the two, to which these respective attributes are mutually relevant, each serving as a referent of the other.

But the concrete working out of all such tendencies depends on the second set of conditions – namely the arenas for their concretization. These conditions included, first, the respective concrete economic political-ecological settings, whether they were small or great societies, whether they were societies with continuous compact boundaries, or with cross-cutting and flexible ones. Second was the specific historical experience of these civilizations – especially in terms of mutual penetration, conquest, or colonization.

Internal Transformation of the Axial Civilization: Secondary Breakthroughs and the Crystallization of Modern Civilization

One of the most important aspects of the dynamics of Axial civilizations was the possibility of development within them of internal transformation, of what has been designated as secondary breakthroughs, the most important illustrations of which have been Second Temple Judaism and Christianity; later Islam, Buddhism, and to a lesser extent Neo-Confucianism, all of which developed out of heterodox potentialities inherent in the respective 'original' Axial civilizations.

But the most dramatic transformation from within one of the Axial civilizations has probably been that of modernity as it first emerged in Western Europe and as it expanded – encompassing most parts of the world, giving rise to development of multiple, continually changing modernities.

The cultural and political program of modernity constituted in many ways a sectarian heterodox breakthrough in the West and Central European Christian Axial civilization. Such transformation took place through the Reformation and in the Great Revolutions, in which there developed very strong emphasis on the bringing together of the City of God and the City of Man. It was in these revolutions that sectarian activities were taken out from marginal or segregated sectors of society and became interwoven not only with rebellions, popular uprisings, movements of protest but also with the political struggle at the center, and were transposed into the general political movements and the centers thereof.

It was above all in the French Revolution that the fully secular transformation of the sectarian anti-nomian orientation with strong Gnostic components took place. It was epitomized in the Jacobin orientations which became a central component of the modern political program – to reappear yet again forcefully, as Alain Besancon has shown, in the Russian Revolution, and later in the Chinese and Vietnamese revolutions.

The strong sectarian roots of modernity and of the tensions between totalistic Jacobin and pluralistic orientations which developed in Europe find very strong resonance in the utopian sectarian traditions of the Axial civilizations. It is also the religious roots of the modern political program that explain the specific modern characteristics of what may be seen as the most antimodern contemporary movements – namely the various fundamentalist movements which, contrary to the view which defines them as traditional, constitute a new type of Jacobin movement constructing tradition as a totalistic ideology.

The Cultural and Political Program of Modernity: Premises and Antinomies

The cultural and political program of modernity, as it crystallized first in Western Europe from around the seventeenth century, was rooted in the premises of the European civilization and European historical experience and bore these imprints – but at the same time it was presented and perceived as being of universal validity and bearing.

The radical innovation of this cultural program as it developed in Europe lay first in the 'naturalization' of man, society, and nature; second in the promulgation of the autonomy and potential supremacy of reason in the exploration and even shaping of the world; and third the emphasis on the autonomy of man, of his reason and/or will.

In connection with these orientations there took place far-reaching transformations of the symbolism and structure of modern political centers, as compared with their predecessors in Europe or with the centers of other civilizations. The crux of this transformation was first the charismatization of the political centers as the bearers of the transcendental vision of the cultural program of modernity; second the development of continual tendencies to permeation of the peripheries by the centers and of the impingement of the peripheries on the centers, of the concomitant blurring of the distinctions between center and periphery; and third was the incorporation of themes of protest as basic, legitimate components of the premises of these centers. These themes became central components of the project of emancipation – a project which sought to combine equality and freedom, justice and autonomy, solidarity and identity of modern political discourse and practice. The program also entailed a distinctive mode of the construction of the boundaries of collective identities. Such identities were not taken as preordained by some transcendental authority, but continually constructed and continually problematized, becoming also foci of political struggle by national and ethnic movements.

The civilization of modernity as it developed in the West was from its very beginning beset by internal contradictions, giving rise to critical discourse which focused on the tensions and contradictions between its premises, and between these premises and institutional development. The most important such tensions in this program were first that between totalizing and more pluralistic conceptions of its major components – of the very conception of reason and its place in human life and society, and of the construction of nature, of human society and

its history; second, between reflexivity and active construction of nature and society; third, those between different evaluations of major dimensions of human experience; and fourth between control and autonomy.

These basic tensions, contradictions, and antinomies inherent in the cultural program of modernity were continually played and worked out in major institutional arenas.

Continually Changing Multiple Modernities

It was out of the conjunction of these cultural orientations with the development of market, commercial, and industrial economies; with the crystallization of a new political and state order; and with military and imperialist expansion, that the civilization of modernity emerged. Its crystallization and expansion were not unlike those of the expansion of all historical civilizations. What was new was first that the great technological advances and the dynamics of modern economic and political forces made this expansion, the changes and developments attendant on them and their impact on the societies to which it expanded much more intensive. The expansion, through the use of military, political, and economic forces, of modern civilization which took place first in Europe and then beyond it continually combined economic, political, and ideological aspects and forces, and its impact on the societies to which it expanded was much more intense than in most historical cases. It spawned a tendency – rather new and practically unique in the history of mankind – to the development of universal, worldwide institutional, cultural, and ideological frameworks and systems. Yet all of these frameworks were multicentered and heterogeneous, each generating its own dynamics.

Of special importance in this context was the relative place of the non-Western societies in the various – economic, political, ideological – international systems which differed greatly from that of the Western ones. It was not only that it was Western societies which were the 'originators' of this new civilization. Beyond this and above all was the fact that the expansion of these systems, especially insofar as it took place through colonialization and imperialist expansion, gave to the Western institutions the hegemonic place in these systems. Yet it was in the nature of these international systems that they generated a dynamics which gave rise both to political and ideological challenges to existing hegemonies, as well as to continual shifts in the loci of hegemony within Europe, from Europe to the United States, then also to Japan and East Asia.

But it was not only the economic, military-political, and ideological expansion of modernity from the West throughout the world that was important in this process. Of no lesser significance was the fact that this expansion has given rise to continual confrontation between the cultural and institutional premises of Western modernity and those of other civilizations. Thus, while the spread or expansion of modernity has indeed taken place throughout most of the world, it did not give rise to just one civilization, one pattern of ideological and institutional response, but to at least several basic variants – and to continual refracting thereof.

Consequently, multiple modernities have emerged. These civilizations, which share many common components and which continually constitute mutual reference points, have been continually unfolding, giving rise to new problematiques and reinterpretations of the basic premises of modernity. All these attest to the growing diversification of the visions and understanding of modernity, of the basic cultural agendas of different sectors of modern societies – far beyond the hegemonic vision of modernity that was prevalent before. The fundamentalist – and the new communal-national – movements constitute one of such new developments, in the unfolding of the potentialities and antinomies of modernity.

Such developments may indeed also give rise to highly confrontational stances – especially to the West – but these stances are promulgated in changing modern idioms, and they may entail a continual transformation of the cultural programs of modernity. At the same time the new diversity was closely connected – perhaps paradoxically – with the development of new multiple common reference points, and with a globalization of cultural networks and channels of communication far beyond what existed before.

Clan

Philip Burnham, University College of London, London, UK

Abstract

The definition of a clan as a group of persons who believe themselves to be related by unilineal descent but who are unable to trace genealogical connections linking all members of the group emerged out of a complex intellectual history. Nineteenth-century social evolutionists disagreed whether early stages of society were patrilineal or matrilineal but generally accepted that clans were a typical form of primitive social structure. Clanship was also seen as linked with totemism, as an early form of religion, although Lévi-Strauss later rejected any necessary association between clanship, religious belief in animal or plant ancestors, and group exogamy. Radcliffe-Brown, Fortes, and Evans-Pritchard analyzed clanship as one level within a system of segmentary lineages, but there is analytical value in maintaining a distinction between lineages, with their comprehensive genealogical structures, and clans. The diverse forms of clanship that occur in many parts of the world can be understood in relation to several key variables. Of prime importance is the extent of their capacity for organized collective action, as well as their social networking function for a dispersed clan's members. Many cultures' understandings of clanship, which are often rooted in myth, posit a primordial clan identity that is seen as immutable, much like ethnicity.

The modern definition of the clan, now widely accepted, as a group of persons who believe themselves to be related by unilineal descent but who are unable to trace genealogical connections linking all members of the group, has emerged out of a complex intellectual history stretching back to the Enlightenment. Many social theorists of the eighteenth and nineteenth centuries who were concerned to understand the origins of the state and democracy favored evolutionist explanations Kuper (1988). Some viewed the family as the original form of society which, over the course of human history, had aggregated into progressively larger and more complex kinship-based groupings of clans and tribes, which eventually were transformed into the territorially based political formation of the state. Drawing on the work of Barthold Niebuhr (1828), George Grote (1851), and other historians of Greece and Rome, social theorists such as Sir Henry Maine (1861), Numa Fustel de Coulanges (1876), and Lewis Henry Morgan (1877) used the ancient Greek and Roman kinship groups, the *genos* and the *gens*, as models on which they based their understanding of early stages of social evolution.

Maine's (1861) analysis of the evolution of legal systems, using the example of the Roman *gens* and the concept of agnation, that is, kinship traced through exclusively male, patrilineal descent links, posited a primitive stage of social development in which membership in patriarchal kinship groups defined a person's social status. Maine emphasized that the *gens* was a corporate group which had a legal personality that endured beyond the lives of its individual members, an insight which has been very influential in subsequent work on clans and other forms of descent grouping.

In contrast to Maine's theory of primitive patriarchy, John Ferguson McLennan (1865) and Lewis Henry Morgan (1877) argued that the early stage of social evolution was characterized by group marriage, which meant that paternity was uncertain and kinship was traced in the maternal line. For some authors favoring the theory of primitive matriliny, the term 'clan' was applied exclusively to matrilineal descent groups while *gens* referred to patrilineal groups, a terminological distinction that has fallen out of use in the modern literature. Morgan, whose own research among the Iroquois in New York State had been influenced by Grote's analysis of the ancient Greek *genos*, saw a descent group organization, which he termed the 'gentile' system, as characteristic of much of early human social history. McLennan, basing his reasoning on contemporary reports of female infanticide in India, claimed that primitive societies were obliged, in their struggles for survival, to engage in this population limiting practice, which in turn led kin groups to procure wives by capture from outside their own group. McLennan termed this marriage outside the group 'exogamy,' which came to be seen, by many nineteenth and early twentieth century social theorists, as another characteristic attribute of clanship.

McLennan was also influential in developing the theory of totemism, which built on E.B. Tylor's notion that primitive religion was based on animism, the worship of inanimate objects or fetishes which were believed to be the abodes of spirits. Along with his follower W. Robertson Smith and Smith's student Sir James Fraser, McLennan defined totemism as a system which originally combined animistic religious beliefs with matrilineal descent and exogamy. According to this view, through their ignorance of paternity caused by group marriage and their belief in animism, primitive societies posited links to original animal or plant ancestors. These natural species, which were treated as sacred emblems, or 'totems,' of different clans, were periodically worshipped by clan members in totemic rituals. Emile Durkheim (1912), in his work on the social origins of religion which drew extensively on early ethnographic reports of aboriginal Australian societies, reproduced many of these classic arguments concerning totemism, emphasizing particularly the concept of a sacred social solidarity based on a belief in a shared substance between clan members and their ancestral totemic species. Claude Lévi-Strauss's (1962) subsequent general critique of theories of totemism, which emphasized the lack of a necessary coincidence between totemic species as emblems, exogamous clans, and religious sacrifice, served to unhitch the clanship concept from the pseudohistorical

hypotheses of nineteenth century evolutionism while, at the same time, helping to clarify the classificatory logic operative in cultural categories such as the clan.

The work of the British structural-functionalist A.R. Radcliffe-Brown (1950) and his followers E.E. Evans-Pritchard, Meyer Fortes (Fortes and Evans-Pritchard, 1940), and others between the two world wars, did much to put the study of unilineal descent systems on a firmer ethnographic footing, while refining the conceptual framework for their study. The model of the segmentary lineage, consisting of a nested set of increasingly inclusive corporate unilineal descent groups linked by a comprehensive genealogical structure, is the most well-known outgrowth of their work, with the term 'clan' often being used by these authors to label a particular segmentary level within a lineage system. Although Radcliffe-Brown's (1950: pp. 39–40) definition of the clan, given in the first sentence of this article, has come to be widely used, this application of the term to characterize one of the levels in a segmentary lineage system is not always appropriate and reflects a continuing influence of earlier understandings of totemism, in which descent group exogamy and totemic taboos were taken to be defining attributes of clanship.

Although a definitional contrast between clan and lineage is thus still not always clearly made in the more modern literature, there is analytical value in maintaining a clear distinction since the organizational implications of the two forms of descent grouping are different. Members of a lineage know or claim to know the genealogical connections interlinking all members of the group, and these links, viewed in terms of generation and relative birth order, often provide a basis for calculating relations of seniority or degrees of relatedness between individuals and segments within a lineage. Lineage genealogy can also be the basis for internal segmentation of groups, according to the segmentary lineage model. In contrast, lacking such a comprehensive internal genealogical armature, relations of clanship are categorical in character and typically nonhierarchical within the clan. Persons are members of a clan because of being the offspring either of their fathers or their mothers, with the terms 'patriclan' and 'matriclan' often being used to indicate a clan's mode of recruitment of its members. Although ascending descent links beyond the grandparental or great-grandparental generation are normally of little or no organizational significance, clan members in many societies do nonetheless recognize a founding clan ancestor, who is often of mythical or nonhuman status. Thus, when clans do segment according to putative genealogical links, this is typically 'from the top' with reference to the founding ancestor and his or her children, producing a set of subclan categories that also lack comprehensive internal genealogical structures.

Terminological confusion is also possible in the case of the descent group known as the conical clan, or ranked lineage, which combines characteristic features of both lineages and clans. Such descent groups are internally differentiated into a high ranked, lineage-like, chiefly or noble descent line, and a lower ranked and internally undifferentiated clan-like category of commoners (Kirchhoff, 1959; Friedman, 1979). Chiefly rank in a conical clan is typically based on relative birth order in present and ancestral generations, so that senior sons or daughters of senior ranking ancestors keep careful track of their pedigrees to validate their noble status. Junior offspring of junior ancestors, on the other hand, have little motivation to remember their genealogies, and their affiliation to the group is more categorical, or clan-like, in character. Numerous ethnographers have drawn attention to the structural potential of conical clanship, particularly as a transitional formation between uncentralized, kin-based political systems and centralized chiefdoms or states. Conical clan structures are relatively common in Polynesian societies, such as the Maori, and in southeast and central Asian societies, such as the Mongols. The clans of the Scottish Highlands also displayed such internal ranking (Dodgshon, 1998) during their hey-day from the sixteenth to eighteenth centuries. The Scottish clan chief and his close relatives enjoyed high status due to their close patrilineal connection to the founding clan ancestor. The commoner members of the clan, on the other hand, did not necessarily have blood ties to their chiefs but were bound to their clan by diverse social ties including feudal land tenancy or relations of marriage, as well as real or fictive kinship expressed by a common clan surname.

The term 'clan' is derived from the Gaelic word *clann* meaning 'children of' and came into medieval English usage to describe the kin-based character of early Irish and Scottish societies. But as explained above, members of Scottish clans were not necessarily all blood kin, despite a strong ideology of shared kinship. Recent research by Basu (2005) and others on modern Scottish heritage tourism and the numerous Scottish clan societies in present-day North America has emphasized the inventedness of much of the modern understanding of the Scottish clan, which imagines a clan's members as sharing blood ties, an ancestral territory, a tartan, and other symbols of clan unity.

Systems of clanship occur in many parts of the world and their diversity of form can be understood in relation to several key variables. Of prime importance is their often weak capacity for organized collective action as corporate groups, which is frequently limited or absent due to the spatial dispersal of clan memberships. Particularly in territorially extensive societies with large populations, a clan's members usually reside in many different locations, and there are limited possibilities for the full membership of a clan to meet as a total group. In such circumstances, clans may act collectively on only a few occasions, such as during annual rituals like the aboriginal Australian *corroboree* ceremonies, which clans celebrate to insure the continued fertility of their totemic species. In other cases of spatially dispersed clan membership, a clan may never meet as a totality but simply act as a named category from which localized sets of clan members may be mobilized to pursue collective action as necessary or advantageous.

In addition to their variable capacities for organizing group action, numerous authors have also drawn attention to the potential of clanship systems to serve a social networking function. For example, in West Africa among speakers of the Mande family of languages (Jackson, 1974), a limited set of clan names is found throughout this large zone, and a clan member making a long journey can feel confident of finding members of his or her clan who will provide assistance at the distant destination. Even in cases where the set of clan names changes from one society to an adjacent one, conventional equivalences are often established between clan names to

facilitate the extension of such networks of mutual aid. Similar clan networks have also been noted among North American Amerindian and aboriginal Australian societies.

Although analysts of clanship have frequently conflated it with lineage structure, the logic of clanship is often more a matter of 'sub-ethnicity' rather than 'super-lineage.' Many cultures' understandings of clanship, which are often rooted in myth, posit a primordial clan identity which is seen as immutable, much like many cultures' conceptualizations of ethnicity. It is this theme that Lévi-Strauss (1962) explored in his work on totemism, in which the classificatory logic of clans as social species is seen as sharing the same pattern as cultural classifications of animal and plant species. In such cases, the total number of clans in a society may be quite small and be viewed as unchanging, with the various clanship categories standing in long-term interrelationships of marriage alliance, ritual cooperation, or other modes of mutual exchange or solidarity. In societies where the total number of clan categories is only two, these groupings are conventionally referred to as 'moieties.'

In contrast, some societies have systems of proliferating clans in which it is evident to the analyst, from the presence of large numbers of clans with relatively small memberships in the context of overall population growth, that clans are undergoing segmentation, although this is often not acknowledged by clan members themselves. Such systems of proliferating clanship tend to be found in politically uncentralized societies with high rates of spatial mobility, where local groups frequently split as a mode of dispute settlement. In such cases, it may be posited that, following an episode of intra-clan dispute which has been resolved by group fission and spatial displacement, the members of the resultant new segments have an active interest in denying knowledge of former ancestral interlinkage. Such systems of proliferating clanship, characterized by many small clans that are widely dispersed spatially, are not conducive to the maintenance of the patterns of long-term inter-clan alliance mentioned above.

In some cases, the term 'clan' has also been applied to territorial groups which are recruited both on the basis of unilineal descent and long-term coresidence. Such a usage is common in New Guinea. Here, in-migrant strangers hailing from other clans may initially be welcomed in order to strengthen a localized clan grouping. Over time, cultural theories of personal identity may posit, for example, that through continued consumption of foodstuffs cultivated on the clan's land, the physical nature of such incomers becomes transformed into that of true clansmen, thus converting coresidence in a single territory into shared descent. In effect, as argued by the American kinship specialist George P. Murdock (1949), such a 'compromise kin group' reflects the difficulty of constituting a large scale, residentially unified, and collectively functional kinship grouping on the basis of unilineal descent alone.

As explained above, the concept of clanship is based on a categorical understanding of social grouping which classifies the members of a society into mutually exclusive units, or 'types,' of people. Recent studies such as Rupp's (2011) of the Bangando of the Cameroonian rainforest in Central Africa show how this classificatory logic may be employed by members of a society to conceptualize their relations with the wider world. Thus, while the Bangando themselves are divided into diverse clans (People of the Elephant, People of the Monitor Lizard, People of the Monkey, etc.), their clanship terminology is extended today to encompass new categories of individuals the Bangando now have contact with, such as wildlife conservationists (People of the World Wide Fund for Nature (WWF)), loggers (People of the Timber Camp), or soccer teams (People of the Ball).

Finally, it should be recognized that, in common parlance today, the term 'clan' is often used in a metaphorical way to refer to any group of persons who act toward each other in a particularly close and mutually supportive way. Thus, criminal organizations such as the Mafia may be referred to as 'clans,' in recognition of the ideology of kin-like solidarity that binds their members together, while in post-socialist Eastern European countries, the term is often applied to networks of politically and economically influential persons.

Abstract

At one time legal scholars and practitioners viewed the class action as a quintessentially American civil procedure. Now class actions have spread around the world, to at least two dozen jurisdictions on every continent but Antarctica. All class action procedures share some common features, most importantly that they allow one or more people or entities to represent a much larger group of similarly situated claimants who are not before the court. Specific provisions vary, however. The goals of class actions include efficient case management, access to justice and regulatory enforcement, but priorities assigned to these goals vary across jurisdictions, and are reflected in the design of procedures. Class actions have been used in the United States and elsewhere to seek a wide variety of monetary and nonmonetary remedies for claims ranging from human rights abuse, to environmental disasters to financial wrongdoing. The extensive literature on class actions is largely theoretical but the field has recently attracted the attention of empirical scholars.

A class action is a legal procedure that enables one or a few people or entities to pursue a claim in court on behalf of themselves and other similarly situated claimants who are not themselves before the court. What distinguishes class actions from other forms of collective litigation is its representative character. Because the procedure may extinguish as well as secure the rights of absent parties, its adoption and implementation typically evoke controversy. Although not always articulated, some of the opposition to class actions stems from the understanding that permitting collective litigation has the potential to increase the number of certain types of lawsuits that are too expensive for plaintiffs to litigate on an individual basis. Most of the scholarly literature on class actions addresses normative or technical legal issues but there is a growing empirical literature on economic and socio-legal aspects of class action litigation.

History

The notion that a group of people united by family ties, geography, socio-economic status or other social identity characteristics might have a collective interest in pursuing a claim against a public authority or private person appears to have deep historical roots. Traditional societies' 'blood feuds' are a violent manifestation of a social norm legitimating collective redress for harms inflicted by one member of a clan on another clan's member (Otterbein and Otterbein, 1965). Yeazell (1987) reports multiple instances of group litigation against feudal institutions over property rights in medieval England. Although group litigation gradually died out in England, the tradition lived on in the American colonies.

Early American courts permitted representative group litigation when numerous parties shared a common legal interest. When the U.S. federal court rules were substantially revised in 1938 the revised rules included an updated procedure for what were by then called 'class actions.' But the 1938 class action rule was technically demanding, leading to post-World War II calls to revise it, particularly to facilitate lawsuits seeking the end of racial discrimination. The current form of federal Rule 23 was adopted in 1966 (Hensler et al., 2000). Since that time there have been frequent calls for amendment to address one or more perceived problems with class action practice. Amendments in 2003 left the structure of rule intact, but clarified the timing of class certification and the judge's responsibilities regarding appointment of class counsel, settlement approval and attorney fee awards. All but one U.S. state have class action rules modeled on federal Rule 23.

Until the early 1990s, there were no other countries that permitted collective litigation along the lines of the American class action. Over the next 20 years the global landscape of class actions shifted dramatically, and class actions spread first to Australia and Canada, then to Brazil, and subsequently to Northern and Western Europe, the Middle East and Asia. Today more than two dozen countries have adopted some sort of collective litigation procedure; similar procedures are under debate in other countries (Hensler et al., 2009).

Goals

Efficient case management is the first goal of most class action laws. When large numbers of claims arise out of the same factual and legal circumstances, the result often is to flood one or a few courts with caseloads far beyond their capacity to resolve expeditiously. By allowing a court to decide common issues in a single representative action, the class action eliminates the need to decide essentially the same issue over and over again in individual litigation, saving expensive judicial time. For the same reason, class actions can also save money for a defendant who is the target of hundreds or more almost identical legal claims. Collecting claims in a single action also facilitates settlement, a goal of most courts and many parties. Class settlements are attractive to defendants who prefer capping their liability exposure and avoiding protracted individualized litigation.

A second goal of some class action laws is to increase access to justice for individuals who cannot easily afford legal representation unless they come together as a group to pursue their legal rights. Since 1966, the class action has been the primary

vehicle for bringing claims against the United States federal and state governments charging violations of constitutional and statutory rights (Chayes, 1976; Fiss, 2009). Canadians have also used the class action procedure to pursue rights claims (Kodar, 2012). Whether social impact litigation via class actions and other procedures is effective in achieving social policy goals is sharply contested (Bell, 2004: Llewellyn, 2002; Lobel, 2003: Rosenberg, 2008).

A different sort of access to justice argument is made in favor of individuals and small businesses who have lost small amounts of money as a result of alleged legal violations by defendants who stood to make large sums of money as a result. Proponents of class actions argue that in these circumstances collective proceedings are the only practical way for injured parties to obtain compensation for their losses. This goal of class actions has been dubbed 'collective redress' by European policy-makers and policy advocates (European Parliament, 2012).

The wisdom of litigating over small monetary claims strikes some policy-makers and citizens as questionable, however. Critics of 'small value' class actions find it particularly troubling that the attorneys who represent class members in such suits earn far more in fees than any individual class member receives in compensation for his or her loss. They label these suits 'negative value class actions.' The fact that in some of these cases the class action attorney wins fees that are equal to or are larger than the *total* sum paid to class members makes this use of class actions seem particularly egregious to class action critics. Some class action proponents argue to the contrary, emphasizing that the small value class action is an important tool for regulatory enforcement. According to this 'private attorney general' theory, class actions make an important contribution to deterrence by forcing defendants to pay substantial penalties for illegal behavior (Coffee, 1986; Rubenstein, 2004; Lehav, 2011). From the perspective of law and economics, the division of the defendant's payment between class counsel and class members is immaterial: the total payment constitutes the sanction. However, this argument is often lost on politicians and the general public, and private regulatory enforcement is the most controversial goal of class actions in every jurisdiction that has debated whether to adopt such a procedure.

Description of Class Action Procedures

The common features of contemporary class action procedures are that (1) they allow one or more people or entities to bring a lawsuit on behalf of a class of people or entities that share legal and factual claims arising out of the same event or practice, and (2) the outcomes of the lawsuit will bind the members of the class. The key distinction between class actions and other forms of collective action is that, save for the class representative(s), class members are not before the court. Other forms of collective litigation generally involve aggregating similar claims, each of which has been filed in court.

Generally, jurisdictions only permit representative class actions when the class members are so numerous that it is impractical for all to appear in court ('numerosity') and when the claims share common legal and factual issues ('commonality'). Jurisdictions define numerosity and commonality differently. Some jurisdictions, including the United States, require an onerous certification process to assure that only those civil actions that satisfy the relevant criteria are allowed to proceed in class form; in other jurisdictions, such as Australia, this process is less demanding (Grave et al., 2012). Other key features vary from country to country. The most important of these features are:

- *Scope* (For what sorts of substantive claims may class actions be used?)
- *Standing* (Who is permitted to come forward on behalf of the class?)
- *Remedies* (What will class members obtain if their suit is successful?) and
- *Whether* eligible class members need to 'opt in' proactively if they want to join the class, or need only 'opt out' proactively if they wish to exclude themselves.

U.S. procedural rules are *trans*-substantive, meaning class actions may be filed for a wide variety of constitutional, statutory and common law claims. Most other jurisdictions limit the use of class actions to one or a few domains, such as securities, consumer or anti-trust violations. U.S. class action rules permit any person or organization (e.g., a small business) to represent a class of similarly situated claimants, subject only to a judge's finding that the proposed representative's interests are 'typical' of other class members and that the individual or organization will 'adequately represent' the class members. In many other jurisdictions, only preexisting organizations such as consumer or investor associations or specially authorized nongovernmental organizations or public officials may sue on behalf of a class. In the United States, class members may obtain declaratory or injunctive relief (i.e., a judicial declaration as to the constitutionality or legality of a policy or practice or an order to end or adopt a practice) or monetary compensation. Outside the United States, class members generally are limited to nonmonetary remedies in all or most circumstances. In the United States, in class actions for money damages all people or entities that meet the class definition (e.g., all investors who purchased a certain stock during a specified time period) are deemed to be class members unless they proactively exclude themselves – i.e., 'opt out.' Most other jurisdictions have adopted 'opt in' rules instead (Hensler et al., 2009).

The consequences of these variations in class action features are profound. By permitting any typical class member with adequate resources to represent the class, allowing class members to seek monetary as well as nonmonetary remedies for a wide variety of alleged harms, and not requiring eligible class members to pro-actively declare their interest in joining the litigation, U.S. class action rules facilitate broad use of class action procedures for diverse purposes. By limiting scope, standing and remedies and requiring that class members 'opt in,' other jurisdictions limit the use of class actions (Hensler, forthcoming).

Class action procedural rules operate within distinctive legal regimes, with different substantive laws. Some statutes specify that individuals may use a class action to claim remedies for violation of rights granted by the statute; other statutes specifically *prohibit* use of a class action procedure to claim remedies for statutory violations, forcing those who wish to

litigate to file individual claims. Judicial interpretations of the relationship between substantive laws and class action procedural rules also affect whether and how frequently class actions are filed. For example, if each investor who claims to have lost money in trading on the stock market as a result of a corporation's failure to properly disclose relevant information has to prove individually that she relied on whatever information was disclosed, then investors are unlikely to be able to proceed in class form. Securities class actions in the United States became more viable in 1988 when the U.S. Supreme Court held in *Basic v. Levinson* that instead of each class member needing to prove individual reliance, the class as a whole needed only to show that the corporation perpetrated a 'fraud on the market' that affected stock prices. But U.S. consumer class actions became less viable in 2011 when the Supreme Court held in *AT&T Mobility v. Concepcion* that under the Federal Arbitration Act of 1925, an arbitration provision in a consumer contract could preclude consumers from proceeding in class form both in court and in private arbitration.

The substantive legal rules that most affect the use of class action procedures, however, are those that pertain to litigation financing. Every jurisdiction has rules about how to apportion the cost of litigation that were fashioned for individual litigation. In the United States, each party bears its own costs, win or lose, except in certain circumstances specified by statute. In most other countries, the losing party is required to pay the prevailing party's expenses. To assure that the defendant's costs will be covered if it prevails, the plaintiff may be required to post a bond at the time she files her lawsuit. Usually the actual amount paid by the loser is determined by a judge or other court official, sometimes according to a published cost schedule. In the United States, a lawyer is allowed to represent a party on a contingent or speculative basis, meaning that the lawyer is only paid if her client prevails. Typically, in individual litigation, the plaintiff lawyer enters into a contingent fee contract with her client, specifying that her client will pay her a share of the damages (e.g., one-third) if the client prevails and nothing if the client does not prevail (Kritzer, 2004). Defense lawyers are most often paid on an hours-and-expense basis, although sometimes defendants enter into contingent contracts. In most other jurisdictions lawyers are not allowed to enter into contingent fee contracts in which their pay will depend on the amount of money the plaintiff wins, although some jurisdictions do allow attorneys to represent plaintiffs on a conditional ('no win, no pay') basis (Emons and Garoupa, 2006), and some parties pay 'success fees' to their lawyers.

In the United States, special rules on selecting and paying lawyers have evolved for class actions. These rules incentivize lawyers to bring class actions and ensure that all class members contribute to the cost of successful class litigation. Except in securities class actions that are governed by a special statute, the judge appoints the class counsel and if the class prevails at trial or negotiates a settlement with the defendant, the judge decides how much the lawyer will be paid. (U.S. rules for securities class actions are governed by the *Private Securities Litigation Reform Act of 1995*. The legislation directs the judge to appoint as class representative the investor with the greatest stake in the litigation; that investor is then free to select the lawyer for the class.) Often, the judge specifies an amount that is a fraction of the total amount the class obtained (Eisenberg and Miller, 2010). The result is that all of the class members contribute to paying the attorneys' fees.

In most other jurisdictions, the same legal financing rules that apply to individual litigation apply to class actions. These rules make it much less attractive, compared to the United States, for individuals to come forward to represent a class and for lawyers to agree to serve as class counsel. The class representative contracts with the lawyer to represent the class, is subject to adverse costs if the class does not prevail, and may have to post bond when the class action is filed. None of the other class members share these costs or risks. If conditional fees are permitted, the lawyer will fund the litigation while it is ongoing; otherwise, the class representative will have to pay legal fees and expenses until the case is resolved. The successful class counsel who accepted the case on a conditional basis may or may not receive any risk premium for doing so.

To address financial constraints on class actions (and other complex commercial litigation), an increasing number of jurisdictions outside the United States have endorsed the introduction of third-party litigation financing into class action practice (Kalajdzic et al., 2013). Litigation financers view litigation as an investment opportunity. They contract with class members to take on the risk of adverse costs and pay the class counsel to maintain the litigation; in return, if the class prevails, the financers – typically publicly traded companies, hedge funds or other private investment companies – take a share of each class member's compensation. The introduction of third-party litigation financing facilitates class actions with good potential for large monetary damages but does nothing to encourage social impact litigation seeking declaratory or injunctive relief.

Uses

Most of what we know about how class actions are used in different jurisdictions derives from reported judicial decisions and commercial media. No jurisdiction maintains a comprehensive database of class action filings (as distinct from nonclass civil filings) and no jurisdiction tabulates the number of class actions filed by substantive case type. Not all judicial decisions relating to class actions are published. Mass media focus on cases arising out of vivid circumstances, such as environmental disasters and financial scandals. As a result we know about examples of the use of the class action procedure, but not how representative these examples are.

Social Impact Litigation against Governments

In the United States class actions have been used to shape public policies governing schools (e.g., racial segregation, school financing), prisons (e.g., race, ethnic and religious discrimination, health services, crowding), social safety net programs (e.g., aid to women and children), taxation and a host of other issues (Hensler et al., 2000; Burke, 2003; Farhang, 2011). In Canada class actions have been used to shape policies regarding the treatment of indigenous people (Kodar, 2012) and same sex couples. However, outside the U.S.

and Canada, this use of class actions appears to be rare. In Israel the class action statute limits class actions against the state (Magen and Segal, 2009) and in China social activists who have attempted to bring class actions that implicate government policies have been jailed.

Social Policy Litigation against Industry

American lawyers have long used class actions against individual businesses to shape public policies governing the workplace (e.g., racial, ethnic, gender, age and disability discrimination, sexual harassment). More recently, social activists in many jurisdictions ave teamed with trial lawyers and government officials to bring lawsuits against the tobacco, gun, alcohol and food industries seeking changes in production and marketing practices as well as monetary compensation. These suits combine 'cause lawyering' strategies (Scheingold, 2004; Sarat and Scheingold, 2006) with entrepreneurial litigation tactics. Activists argue that legislative efforts to regulate behaviors that are hazardous to public health and safety have been stymied by corporate lobbyists. They see litigation as a potentially effective tool of overcoming rent-seeking behavior. The resulting litigation has taken diverse forms, including (in the United States) coordinated lawsuits brought by state attorneys general on behalf of their citizens (sometimes termed *parens patriae* suits), single lawsuits brought by local government officials, individual tort suits seeking compensation for wrongful death and personal injury and private class actions. The multi-billion settlement with the tobacco industry in the United States was the result of coordinated state attorneys general actions, not class actions (Mollenkamp et al., 1998; Zegart, 2000). However, in Brazil, Bulgaria, Canada, Israel and Spain class actions have been filed against the tobacco industry. U.S. litigation against the gun industry has been a mix of public and private individual and class action lawsuits (Lytton, 2009). A large fraction of these social policy lawsuits have failed. However, by calling attention to industry practices that activists allege are harmful to the public, they may have long-term effects on market behavior and public policy.

Mass Accidents and Environmental Disasters

In the United States, the judiciary has long thought that the large numbers of personal injury and property damage claims that often result from mass catastrophes are not suitable for class treatment because of the likelihood of significant differences among class members (Hensler et al., 2000). Notwithstanding this general policy, U.S. federal judges have certified money damage class actions in some high profile environmental catastrophes, such as the *Exxon Valdez* tanker oil spill in Alaska and the British Petroleum *Deepwater Horizon* explosion and subsequent oil spill in the Gulf of Mexico. In some other jurisdictions, class action procedures have been adopted specifically to address environmental contamination or are provided for in environmental protection statutes. For example, Indonesia adopted a class action procedure in response to an environmental nongovernmental organization's legal activism (Santosa, 2009). A massive collective litigation on behalf of Ecuadorian indigenous peoples seeking compensation for environmental contamination from Chevron proceeded in Ecuadorian courts under an environmental protection statute (Gomez, 2013).

Product Safety and Marketing

Although mass product defect claims have been a feature of United States civil litigation for several decades, consistent with the general policy disfavoring class certification of personal injury and property damage claims, few of these mass tort suits have been certified as class actions. An attempt to certify a massive asbestos injury class action was overturned by the U.S. Supreme Court in 1997 (Hensler, 2005–06) and more recent attempts to obtain class certification of pharmaceutical product liability claims have also failed (Silver and Miller, 2010). The Netherlands collective settlement program, however, was adopted specifically to enable a mass settlement of personal injury claims associated with the pharmaceutical product DES (Tzankova, 2012). Chinese activists have attempted to use collective litigation to obtain compensation for injuries associated with contaminated milk and other products but were prevented by the national government from doing so (Liu, 2009).

Economic Transactions

Worldwide the most common use of class action procedures appears to be with regard to market activities. Hensler et al. (2000) estimate that securities and consumer class actions accounted for more than half of all U.S. class actions in the mid-1990s, the most recent period for which these data are known. About half of all Australian federal class actions filed since 2004 pertained to securities, investment advice, and consumer transactions (Morabito, 2009). Although a mass product defect litigation was the inspiration for the adoption of the Netherland's collective settlement act, the five class actions that have followed since all pertained to securities or investment products (Hensler, 2011).

Reparations

Human rights activists in several jurisdictions have attempted to use the class action procedure to obtain compensation from governments and private actors. Although all of these suits seek money damages, those who bring or promote them often are seeking public admission and recognition of harms they or their ancestors suffered as a result of the defendants' denial of their fundamental rights. African-American activists have sought, so far unsuccessfully, to obtain reparations for the enslavement of their ancestors by private parties acting under public law (Fortson, 2004). African-American farmers and Native Americans have been more successful in obtaining compensation from the U.S. federal government for discrimination in payment of agricultural benefits and management and distribution of trust funds (Fortson, 2004). Holocaust survivors and in some instances their descendents have obtained compensation for bank policies that denied children and other relatives access to accounts that had been set up by victims of Nazi atrocities and for industrial slave labor (Authers and Wolffe, 2002: Bazyler, 2003; Neuborne, 2002: Schapiro, 2003). Canadians have received compensation for abusive

practices in residential schools to which the government consigned indigenous children. In class and non-class litigation, victims of sexual abuse by Catholic priests have obtained compensation from Catholic churches in the United States and Canada, in amounts that in some instances resulted in diocesan bankruptcies. Some class action suits brought in U.S. courts against multi-national corporations alleging they were complicit in killing, torture and other abuse of workers in third-world countries have been successful, although others were not. In all these instances, although the direct objective of the class litigation was monetary damages, an equally important – if not more important – goal was bringing culpable parties to account. Because of the media attention they receive, class actions of this sort may achieve some measure of success in meeting their social justice goals even when they fail to obtain monetary compensation for victims (Lobel, 2003).

Scholarship

Perhaps not surprising given that the class action is a creature of statutory law and legal procedural rules, doctrinal analyses dominate the scholarly literature. In addition, there is a vast theoretical literature on class actions. Early work was authored almost exclusively by Americans but today the subject is attracting scholars from other parts of the world (Klemont and Procccia, 2013). Law and economics scholars, who dominate the theoretical literature, focus on the agency problems posed by representative class litigation, particularly in small value class actions where the class counsel's interests outweigh the interests of any individual class member (Coffee, 1983, 1985; Hay, 1997; Macey and Miller, 1991). Legal scholars writing from a legal ethics perspective have also focused on these issues, in some instances drawing attention to what the authors view as particularly egregious examples of a mismatch between the class counsel's and class members' interests (Koniak, 1995; Koniak and Cohen, 1996; Wasserman, 2000). With a few exceptions (Silver and Miller, 2010; Erichson, 2000, 2003) these scholars have ignored similar agency problems posed by nonclass mass litigation in which large numbers of individual claims are aggregated for pretrial development and resolution.

Empirical scholarship on class actions has emerged more recently. The U.S. class action rule requires the presiding judge to approve any class settlement negotiated by the class counsel and defendant and also to award fees and expenses to the prevailing class counsel. Federal judicial decisions including these amounts are published and similar state judicial decisions are increasingly available. As a result there is more information available on class action settlements than for the settlements of ordinary civil litigation, which are regarded as private in the United States as elsewhere. Law and economics scholars have assembled datasets containing this outcome information and analyzed the relationship between settlement amounts and attorney fee awards, by type of case (Eisenberg and Miller, 2010; Fitzpatrick, 2010). The consistent finding for these U.S. cases is that the percentage of settlements awarded to attorneys as fees is negatively correlated with the amount of the settlement. Most settlements offer cash payments to class members, sometimes in addition to other remedies. Mean and median settlement values vary substantially across case types, with commercial matters such as securities and anti-trust class actions yielding the highest average values and labor and employment and civil rights cases yielding the lowest average values (Fitzpatrick, 2010). (In the United States, unlike many other jurisdictions, federal and state courts of first instance have jurisdiction over labor and employment suits.)

Although quantitative analyses of published judicial opinions approving class action settlements shed empirical light on one of the key class action controversies, the relationship between settlement amounts and attorney fees awards, they leave many other important questions unanswered. For example, information on disposition patterns that might indicate the proportion of cases deemed nonmeritorious by judges is scanty. Information on the relationship between negotiated settlement amounts and aggregate losses class members claim is virtually nonexist. Nor is there much information on what proportion of negotiated and judicially approved settlement funds is actually paid by defendants to class members. Because of the lack of comprehensive reliable data on dispositions and pay-outs, Hensler (forthcoming) concludes that it is impossible currently to assess whether class actions generally play a beneficial regulatory enforcement role.

A second line of empirical scholarship on class actions is more qualitative, comprising case studies of small and nonrandom samples of class action lawsuits (Hensler et al., 2000). Because of the strong doctrinal orientation of legal scholarship in most non-US jurisdictions, scholars outside the U.S. are just beginning to conduct these sorts of socio-legal studies of collective litigation (Hensler et al., forthcoming; Liu, 2009; Llewellyn, 2002; Voet, 2013). As a result, the extant literature largely focuses on U.S. litigation.

Qualitative case studies provide thick descriptions of class action litigation processes, highlighting the tensions within a legal regime that incentivizes private lawyers to bring litigation in pursuit of public goals such as structural reform and regulatory enforcement. Scholars as well as journalists have written book length case studies of selected high-profile class action lawsuits that provide vividly detailed stories of how such litigation enfolds. These tend to focus more on the heroic dimension of cause lawyering but also provide insights into the principal-agent problems inherent in representative litigation that have been the focus of more theoretically oriented law and economics scholars (Roberts and White, 1999; Bingham and Gansler, 2003; Schuck, 1986; Zegart, 2000; Schapiro, 2003; Kluger, 2011). To date, neither the quantitative nor qualitative scholarship has been sufficient to test fully the theoretical propositions that have preoccupied class action legal scholars since the advent of the modern U.S. class action rule.

Class Consciousness

Jesus de Felipe-Redondo, University of Michigan, Ann Arbor, MI, USA

This article is a revision of the previous edition article by P. Ansart, volume 3, pp. 1931–1933, © 2001, Elsevier Ltd.

Abstract

'Class consciousness' has been employed in two different but related ways: (1) as the awareness that the members of a class (generally the working class) have of their 'objective' class interests and aspirations, and (2) as a sense of class belonging that adopts different shapes in specific times and places. Both concepts, especially the first one, were fundamental categories of analysis and debate in Marxist and academic studies on class. The evolution of the different explanations they generated mirrors the theoretical changes in sociological and historical theory since the end of the nineteenth century.

Class Consciousness

The term 'class consciousness' represents two different, but related, concepts. The first one refers to the awareness that the members of a social class, usually the working class, have of their common class interests (what is called the 'principle of class identity'). These shared interests are considered to be opposed to those of other classes, especially the bourgeois class (the 'principle of class opposition'). Awareness of this antagonism makes workers fight to end class conflict by transforming social organization. This final goal leads to identification of class consciousness with socialist (particularly Marxist) aspirations that provide a general vision of a classless society (the 'principle of totality').

This first concept has a theoretical character. It plays a crucial role in socialist, especially Marxist, explanations of human action and historical change. Indeed, Marxist thinkers coined and developed the term at the end of the nineteenth century. Conversely, the second meaning is eminently descriptive. It refers to a set of political attitudes, cultural traditions, and moral values shared by the members of a class. Here 'consciousness' does not necessarily imply the awareness of underlying, 'objective' class interests, but rather the specific and contingent ways in which individuals perceive their class position. For this reason, this second concept is employed as synonym of 'class identity,' 'class subjectivity,' or 'class mentality' and, unlike the first concept, it does not articulate a general theory about human action – although it constitutes an object of sociological and historical analysis.

Despite their differences, the two senses are related. The first concept has guided socialist debates since the nineteenth century and has had a significant impact on academic research, especially from the 1940s to the 1980s. It became inseparable from the question of class, and thus it was at the center of the debates on class belonging and human action in sociology and history. By the same token, its gradual disappearance since the 1980s was a consequence of the crisis of class theories and objectivist epistemology. The second meaning spread in part as a response to this crisis, though its current limited use is also a result of the ongoing effects of that crisis (for a different analysis of these two meanings see Wright, 1985).

Marxist Origins

The first concept of class consciousness emerged within the materialist epistemological framework in which most socialist theories were rooted in the second half of the nineteenth century and has been crucial to the development of Marxist philosophy and political theory since then. However, interest in the workers' class conscience was not exclusively Marxist. Many non-Marxist socialists focused on the process through which workers 'became aware' of their supposed class interests. Pierre–Joseph Proudhon, for instance, analyzed "how the working class had distinguished itself from the bourgeois class since 1789 and how it has became conscious of it" (Proudhon, 1865). Karl Marx, on the other hand, did not use the term 'class consciousness,' although his reflection on the relationship between class position and consciousness set the foundation for the concept's elaboration at the turn of the century.

The concept of class consciousness was a consequence of the way in which Marxist thinkers faced a crucial problem: the lack of correspondence between their predictions about workers' conduct and workers' real actions, that is to say, between Marxist theory and empirical observation. Marxist predictions were based on a specific conception of social organization and its effects on individuals' conduct. According to Marx's classic formulation, the implementation of capitalist social relations divided individuals into two classes: the exploitative and parasitical class, represented by the bourgeoisie, and the exploited and dispossessed class, identified with the working class. Since the very existence of the former was based on the systematic exploitation of the later, Marx deduced that capitalist social organization created classes with irreconcilable social interests that spurred workers to fight against the bourgeoisie. Thus, class 'objective' interests rooted in relations of production shaped individuals' consciousness and, therefore, their actions. As Marx (1904) put it in 1859:

> In the social production of their existence, men inevitably enter into definite relations, which are independent of their will, namely relations of production […]. The totality of these relations of production constitutes the economic structure of society, the real foundation on which arises a legal and political superstructure and to which correspond definite forms of social consciousness. The mode of production of material life conditions the general process of social,

> political and intellectual life. It is not the consciousness of men that determines their existence, but, on the contrary, their *social existence determines their consciousness*.

This is the classical materialist-objectivist assumption that led Marxists to explain workers' consciousness and conduct as being determined by workers' position in productive relations. However, there was a critical flaw in this explanation: the majority of workers did not participate in labor struggles, and those who did were more interested in the improvement of particular labor conditions than in changing social organization. Marx was aware of this problem, but this did not lead him to reconsider the aforementioned materialist-objectivist assumption. Rather, this assumption provided him with an explanation of the workers' conduct. He pointed out that workers' perceptions of themselves and their interests were not necessarily a faithful representation of their 'real being' or 'objective class interests.' Marx (Marx and Engels, 1956) wrote in 1844 that:

> The question is not what this or that proletarian, or even the whole of the proletariat at the moment considers its aim. The question is what the proletariat is, and what, consequent on that being, it will be compelled to do. Its aim and historical action is irrevocably and obviously demonstrated in its own life situation as well as in the whole organization of bourgeois society today.

From this perspective, class position and class consciousness were two different, although related, things. This led Marx to differentiate between 'class against capital' and 'class for itself,' a distinction later interpreted by Marxist intellectuals as the dichotomy between 'class in itself' – the class that emerged in the economic structure – and 'class for itself' – the workers' awareness of their class position and interests (Andrew, 1983). At the turn of the century, class for itself was usually referred to as 'class consciousness.'

Marx argued that class position eventually produced class consciousness – in fact, he considered this process as historically inevitable. However, such an emergence was neither automatic nor immediate, but the product of a gradual process through which workers gradually became aware of their alleged class interests. Marx and later Marxists defined two different sets of factors that hindered this process. First, the slow implementation of capitalism and class relations that delayed the emergence of class in the economic structure in certain countries, for class consciousness could not exist without class in itself. Second, capitalism produced its own 'ideological' justification that misled workers regarding their class interests. Marx mentioned organized religion and nationalism as examples of these ideologies, but for him the most prominent was 'commodity fetishism.' Commodity fetishism masked exploitation by making workers perceive productive relations as an exchange of commodities. Marx used the term 'alienation' to express the consequences of this phenomenon: commodity fetishism 'alienated' workers from the act of production and product of their work, from their own nature as human beings and from other workers, preventing them from acquiring class consciousness. A decade after Marx's death, Friedrich Engels (1893) coined the concept 'false consciousness' to refer to the distorting effect of capitalist ideologies on workers' consciousness – a concept that Georg Lukács later explored and developed.

Thus, concepts such as 'ideology,' 'alienation,' and 'false consciousness' accompanied the formulation of class consciousness as category and object of analysis. Indeed, all of them were inextricably linked because the study of class consciousness was the analysis of its absence. Marxist thinkers assumed that class consciousness did not exist in the present, but would appear in the near future. Meanwhile, workers had an alienated, false consciousness. Therefore, the notion of class consciousness foreshadowed the concepts that referred to its very absence.

The explanation of this absence spurred the development of Marxist analysis and debates. The longer that absence endured, the more sophisticated the thesis of false consciousness. In 1844, Marx was confident about the spontaneous character of the emergence of class for itself. He argued that capitalist development and class struggle were already making workers progressively aware of their class interests: "a large part of the English and French proletariat is already conscious of its historic task and is constantly working to develop that consciousness into complete clarity" (Marx and Engels, 1956). At the end of the century, however, Marxist thinkers were more skeptical. In Karl Kautsky's words, the 'error' of Marx and Engels was that they had 'expected revolution too soon' (Kautsky, 1909). Kautsky, Georgi Plekhanov, and other Marxists observed that, despite capitalist development, the growth of labor conflicts, and intensive socialist propaganda, most unionized workers did not follow their supposed class interests. Moreover, many of those who participated in the growing socialist unions and parties disagreed with Marxist tenets, and even many of those supposedly 'conscious workers' who controlled socialist organizations and proclaimed revolutionary objectives acted in reformist ways.

It was then that class consciousness became a pivotal object of study for Marxists, who went deeper than Marx in exploring the factors that prevented workers from becoming class conscious. Marxist intellectuals identified capitalist ideologies as the main factor that hindered the emergence of class consciousness. As Vladimir I. Lenin wrote in 1902, "The working class spontaneously gravitates towards socialism, but the more widespread (and continuously revived in the most diverse forms) bourgeois ideology spontaneously imposes itself upon the working class still more" (Lenin, 1987). Marxist thinkers began to examine and elaborate Marx' and especially Engels' previous ideas about ideological distortion of workers' consciousness. Lenin's development of Engels' thesis of 'labor aristocracy' and 'embourgeoisement' was one of the results of the new reflections. Marxist intellectuals also focused on questions such as the class consciousness of peasants and why socialism – considered the highest expression of class consciousness – had not developed or had done it weakly and differently in each national case. This was the origin of the question of historical exceptionalism that later spread across academic labor studies (the paradigmatic case is Sombart, 1976).

This process of theoretical development brought new and contradictory analytical perspectives on the very nature of class

consciousness that implied antagonistic political strategies. Eduard Bernstein argued that since the majority of workers from the most developed capitalist countries supported social reforms, working-class consciousness was not revolutionary, but reformist. This particular conception of class consciousness became the basis for Marxist 'revisionism' and social democracy during the twentieth century (Crompton, 1993). In rejecting Bernstein, Rosa Luxemburg stated that political and labor struggles would lead workers to spontaneously overcome reformism and develop a revolutionary consciousness. Lenin, in turn, argued that there were different 'levels of class consciousness' and that organized workers could only spontaneously develop one of them, the limited and reformist 'trade-union consciousness.' He maintained that there was a superior level of consciousness, namely 'socialist' or 'revolutionary' consciousness, that workers could only acquire through the guidance of Marxist intellectuals (the socialist vanguard or intelligentsia). This conception of class consciousness became the theoretical pillar for radical Marxist left and communism in the twentieth century (Mayer, 1997).

In this debate, the concept of class consciousness underwent two significant transformations. First, its meaning changed according to the new approaches that divided Marxism. From Marx's perspective, there was only one kind of consciousness that reflected workers' 'real' interests. At the turn of the century, Marxist intellectuals talked of several kinds of class consciousness (reformist, revolutionary, socialist, communist, etc.). This implied that workers could develop different forms of representation of their class experiences and aspirations and that it was necessary to study how these forms of consciousness changed (or could be changed) into others. In a certain way, this idea was one of the roots of the second, descriptive meaning of class consciousness since it entailed the idea that the same class position could be represented in dissimilar ways (through different kinds of consciousness) that produced specific types of conduct.

Second, the Leninist perspective brought the paradoxical idea of 'party vanguard,' that is, a group mainly composed of middle-class individuals that became class conscious before the mass of workers (Bottomore, 1971). This idea led some Marxist intellectuals to argue that 'revolutionary'/'socialist' class consciousness was not a mere product (and could appear independently) of the grade of development of class in itself due to the influence of certain cultural, political, and ideological factors. From this perspective, the relationship between class belonging and class consciousness was more complex than previously thought. Consciousness itself was an autonomous factor that interacted with class position in a dialectical way.

The Russian Revolution in 1917 had a decisive impact on this change of perspective. The triumph of a socialist revolution in a country with a weak industrial working class led Marxist intellectuals such as Lukács, Karl Korsch, and Antonio Gramsci to revise crucial aspects of previous theories of class consciousness in the 1920 and 1930s. These authors gave greater importance to the ideological, political, and cultural factors – including the Marxist theoretical tradition itself – that shaped class consciousness. Furthermore, they described the relationship between consciousness and class position in dialectical terms, thus nuancing explanations based on economic determinism (Goldman, 1971). Lukács (1971), the most important analyst of the question of class consciousness, used the concept of 'reification' to explain the strong influence of bourgeois ideologies on workers' minds and distinguished between 'psychological' and 'ascribed'/'imputed' consciousness. Drawing from a Leninist perspective, he analyzed how the socialist intelligentsia played a crucial role in transforming workers' psychological (false) consciousness into class (ascribed) consciousness. Lukács thought that subjective factors contributed to this process, including Marxism itself. He pointed out that while workers experienced capitalist relationships in their workplace, it was the mediation of Marxist theory that provided them with an explanation of these experiences of exploitation and a solution to them. Thus, Marxism was an active, mediating force that contributed to creating, rather than to merely representing, class consciousness – a thesis ultimately rejected by Soviet Marxists (Eyerman, 1981; Mészáros, 1971).

Lukács, like other Marxists, emphasized the historical and necessary transition from false consciousness to class consciousness (Wright, 1985). Gramsci's view represented a crucial difference on this point. From Gramsci's perspective, historical necessity and class economic determinism had less importance, while cultural factors were crucial for the formation of class consciousness. For Gramsci, class consciousness was not a mere subjective representation of the workers' class position, but a cultural product of workers' reflections on their labor situations (Eyerman, 1981). In other words, if workers became agents of historical change it was not because class position determined them to be so, but because of the way they made sense of that position. Workers were agents of change not because they were proletarian, but because they thought of themselves as proletarian:

> One has only to think of the prominent use that Socialists make of the terms 'consciousness', 'class consciousness', and 'socialist and proletarian consciousness'; implicit in this language is the philosophical conception that one 'is' when one 'knows', or 'has consciousness of', his own being. A worker 'is' proletarian when he 'knows' his truth and works and thinks according to this 'knowing'. (Gramsci, 1984)

Gramsci thought of class consciousness as largely a cultural phenomenon derived both from the workers' experiences, and common practices and reflections about their class position through the cultural traditions and concepts that constituted their perspectives of the world. Workers' consciousness was composed of several cultural and ideological elements, some of which were shared by the dominant classes. Gramsci argued that some ideological trends aspired to organize these reflections and perceptions, creating a prevailing 'common sense' that determined workers' interpretations and actions. The crucial goal for Marxist organizations was precisely to build a 'cultural hegemony' through these elements, fighting against the hegemonic aspirations of other trends and institutions – such as Catholicism and the Church in the Italian case (Eyerman, 1981).

These dialectical perspectives on class consciousness had a limited influence in the Marxist debate. Mainstream explanations assumed the Leninist thesis that (socialist/revolutionary)

class consciousness mirrored class position, and that when this did not occur it was because of capitalist ideological distortion. However, Lukács' and Gramsci's contributions shared an important commonality with the Leninist approach: all of them introduced or further elaborated concepts that referred to the absence of class consciousness (labor aristocracy, levels of class consciousness, reification, false consciousness, hegemony, etc.). Thus, in the 1930s studies on class consciousness had developed a complex and refined set of analytical tools and explanatory theses in order to explain the nonexistence of such consciousness and its possible modes of development.

Academic Debates

Marxism's growing influence in the universities from the 1930s onward contributed to the introduction of the concept of class consciousness into historical and sociological academic studies. Class consciousness became one of the central categories in the analysis of the relationship between social structure and human action. From the 1940s through the 1980s, it was particularly used in studies on social stratification and the history of the labor movement (Crompton, 1993). These analyses also introduced the problem of the absence of class consciousness and spurred debates on questions such as development of class consciousness among white collar workers, peasants, and the bourgeoisie. The problem of the lack of class consciousness had been particularly evident since the 1950s, when several sociological studies showed that most workers in several western countries pragmatically accepted the capitalist order. These studies pointed out that although many workers presented themselves as members of the working class in social or cultural terms, class consciousness was quite limited. Moreover, any radical ideas held were closer to left-populist ideologies than to socialism. Some authors even stated that working-class culture and workers' enthusiasm for collective action were fading away due to the impact of mass society and commercial capitalism (Savage, 2000).

However, since Marxist researchers assumed that there was a direct relationship between class position and consciousness, they kept looking for factors that promoted or hindered development of class consciousness. As sociologist David Lockwood (1958) argued in his study of the blackcoated workers, "To study the class consciousness of the clerk is to study the factors affecting his sense of identification with, or alienation from, the working class." In dealing with this question, researchers incorporated new perspectives and concepts such as the Weberian notion of 'status.' Thus, in trying to explain the British workers' gradual withdrawal of support to the Labor Party in the 1960s, Lockwood, John H. Goldthorpe, and other British Marxist sociologists argued that different perceptions of labor status divided the English working class and thus prevented the rise of class consciousness (Goldthorpe et al., 1968).

The political and social context of the 1960 and 1970s, with the crisis of the labor movement and the rise of the new social movements, made researchers reexamine the relationship between class position and consciousness and consider the impact of cultural, political, and subjective factors on workers' class consciousness. Some authors distinguished between class consciousness and other types of workers' consciousness and studied the mutual influences between them. A famous 1966 article by Lockwood initiated a debate on the distinction between class consciousness and other forms of 'class imagery' (Bulmer, 1975). Alain Touraine (1968) differentiated between 'workers' consciousness' and 'class consciousness' and argued that the latter was not a consequence of class position but the result of a specific and rarely found combination of the principles of class identity, opposition, and totality. Michael Mann (1973) added a fourth principle, the 'vision of an alternative society without classes.' He stated that each of the four principles could exist without any of the others and that their multiple combinations explained the diversity of workers' kinds of consciousness. Anthony Giddens (1973) separated 'class awareness' from 'class consciousness' and 'conflict consciousness' from 'class consciousness,' and focused on the factors that determined the transformation of one form of consciousness into another.

The new perspectives assumed that certain ideological forms previously considered 'false' were active forces in molding workers' subjectivities. Eventually, this idea led some researchers to distance themselves from the old dichotomy of class/false consciousness. According to Tom Bottomore (1971), social researchers had "passed out of the era in which the real consciousness of social groups, expressed in their beliefs and actions, could be discussed as mere 'psychological', 'false' consciousness, and be contrasted with the 'rational consciousness' enshrined in the ideology of a Communist party." In the 1960s and 1970s, many authors criticized economic determinism and leaned toward the study of the dialectic influences between class position and consciousness. In so doing, they explored the arguments developed by Lukács and Gramsci – as well as Marx' recently discovered Grundrisse. Class consciousness began to be perceived as a complex form of subjectivity that emerged in relation to several cultural and political factors and had a dynamic and relational character derived from its relationship to labor experiences and conflicts. Some authors began to argue that class was not a 'thing' (a static object of analysis), but a relational, historical process of creation of a collective political subject, which was mirrored in the ongoing formation of class consciousness. These authors felt increasingly uncomfortable with conventional quantitative methodology and defended qualitative approaches (Savage, 2000, 2005; Fantasia, 1995).

A new conception of class consciousness that entailed a greater attention to the hybridization between class position and cultural and political factors progressively arose from these changes. The most influential author in this 'cultural turn' was the historian Edward P. Thompson (1968). In 1963, Thompson argued that economic conditions did not have a direct impact on workers' minds. Rather, they were 'experienced' in specific ways by workers, who interpreted these experiences through the available cultural and political traditions. Class consciousness was the outcome of this interpretation.

> Class consciousness is the way in which these experiences are handled in cultural terms: embodied in traditions, value systems, ideas, and institutional forms. If the experience appears as

> determined, class consciousness does not. We can see a logic in the responses of similar occupational groups undergoing similar experiences, but we cannot predicate any law. Consciousness of class arises in the same way in different times and places, but never in just the same way. (Thompson, 1968)

From this viewpoint, class consciousness was a historical and relational process in which cultural and economic factors intertwined in complex ways. Class, as subject of historical change, appeared only when workers developed class consciousness, and thus the distinction between class in itself/for itself was called into question. Thompson stated that political languages and cultural traditions molded class consciousness into specific cultural shapes. This meant that it was not possible to distinguish between 'pure' and 'spurious,' 'truer' and 'falser' forms of class consciousness. Consciousness was neither false nor true, but simply what it was (Thompson, 1977). There was not a single model of class consciousness, but different variations depending on cultural and historical circumstances. This entailed the transformation of the problem of exceptionalism in the history of labor movement into the analysis of regional 'variations' of class consciousness and formation (Katznelson and Zolberg, 1986).

The abandonment of the class/false consciousness dichotomy meant a break with previous perspectives. Thompson's work inspired a new generation of historians and sociologists in the 1970s and 1980s (Savage, 2000). These researchers defined and incorporated into their analysis a growing set of cultural factors and sources of identity, including race and gender (Fantasia, 1995). However, this theoretical change eventually put the concept of class consciousness into question. In the 1980s and 1990s, new studies showed the greater importance of non-class identities in explaining workers' actions. In what is considered a general crisis of the class and objectivist paradigm, these studies not only called the category of class consciousness into question, but also criticized the validity of the objectivist epistemic framework in which that category was inscribed. Thus, many authors stated that class consciousness guided analysis toward economic determinism and class teleology and essentialism, including the case of 'culturalist' perspectives based on the Thompsonian notion of experience (Crompton, 1993; Joyce, 1994). The concept of class consciousness was considered to be a key element in what Margaret Somers has called 'epistemology of (class) absence' (Somers, 1997), which prevented researchers from developing deeper analyses of workers' actual identities.

As a result of this criticism, many researchers stopped using the category of class consciousness in the 1980s and 1990s. Class consciousness was replaced by other concepts that mirrored the emergence of new objects of analysis and perspectives on the study of workers' subjectivity with less obvious objectivist connotations, such as 'class identity,' 'class subjectivity,' 'class mentality,' 'class culture,' or 'class dispositions.' This change 'from consciousness to identity' reflected the new orientation of culturalist perspectives that distanced themselves from traditional class issues – although class essentialism and teleology kept guiding the use of these new concepts in many studies (Fantasia, 1995; Savage, 2000, 2005; Bottero, 2004; Somers, 1997).

This does not mean that the term 'class consciousness' has completely disappeared from the academic literature. It is occasionally used in some studies, although it has lost its previous theoretical connotations and assumed a more descriptive sense, referring to the different cultural shapes adopted by the 'sense of belonging to a group.' This is the second concept of class consciousness mentioned in the introduction. Although this second sense had been frequently mixed with the first concept, its relevance grew in the 1990s accompanying the crisis of the latter. Moreover, in this process the term 'consciousness' was gradually identified with that of 'identity,' that is, a set of cultural, moral, and political principles of a particular group of workers that is related to a more general vision of the world (Wright, 1985). This explains the current use of the concept in recent works. According to Mike Savage, "Studying class consciousness (today) involves going beyond studying how someone identifies as a member of a class, and examines the extent to which a person's view about class forms part of a coherent social outlook which can be said to be consistent and organized in terms of class" (Savage, 2000: p. 37). However, since the term 'class consciousness' is still strongly related to the objectivist perspective, some researchers prefer to add adjectives that emphasize the culturally constructed character of such consciousness, creating new terms such as 'discursive class consciousness' (Sayer, 2005).

Class: History of the Concept

Jan Pakulski, University of Tasmania, Hobart, TAS, Australia

Abstract

The history of the concept of class – the evolution of its meaning and deployment – is divided into five periods: (1) the 'prehistory of class'; (2) the formative period of the early nineteenth century, when the concept enters the stage in its Marxist formulations; (3) the period of spread and diversification at the beginning of the twentieth century; (4) the period of ascendancy and proliferation in the second half of the twentieth century; and, finally, (5) the period of decomposition and eclipse starting during the last decades of the twentieth century and lasting till now.

Although 'class' is a very old concept, with its roots in ancient Rome, its contemporary meanings were shaped and reshaped in the context of modern debates triggered by the Industrial Revolution in Europe and its worldwide consequences. In this context, and in the context of Marxist theory and ideology, class started to denote large economically based and polarized (opposed, antagonistic) social groupings, marking the main lines of structured social inequality, conflict, and change in industrializing societies. The concept subsequently evolved together with the changing patterns of social inequality and contestation, as well as the theoretical debates that pitched class against its main concepts-competitors: estate, rank, race, nation(ality), occupational group, stratum, elite-mass, etc. Its popularity had initially increased, and then gradually faded, especially following the declining popularity of Marxism – the theoretical cradle in which the concept of class was embedded – and the collapse of communism at the end of the twentieth century. It is therefore convenient to see the concept of class as (1) theoretically embedded; (2) diverse in its meaning; (3) ideologically implicated, and therefore always politically contested; and (4) historical, that is, evolving together with major social upheavals and their theoretical accounts. It is convenient to divide the history of the concept – its changing meaning and deployment – into four periods:

1. the 'prehistory' of class – the early period when the concept acquired its hierarchical-classificatory meaning;
2. the formative period of the early nineteenth century, when the concept entered the stage in its original (but diverse) Marxist formulations;
3. the period of reshaping at the turn of the nineteenth and twentieth centuries, when the concept was reworked within and outside Marxism;
4. the period of ascendancy and proliferation, when 'class' entered popular discourses and vocabularies – but in an increasingly vague and diverse form; and, finally,
5. the period of further diversification, decomposition, and eclipse that started during the last decades of the twentieth century and continues at present.

Prehistory of Class

The earliest references to 'class' – in its hierarchical-classificatory meaning – are found in ancient Rome, where the summons to military service, called *classis*, ranked citizens into hierarchical divisions (subsequently called *classes*) according to the value of property and expected military equipment and strength. The landless *proletarii* were excluded from the service – they formed the equivalent of ancient 'underclass.' The propertied (land-owning) citizens – those with the right to carry arms and vote – formed seven classes, ranging from armed infantry warrior to those who could afford entire cavalry detachments (Cowell, 1962). This early usage shaped the meaning of the term that became a synonym of a social rank, a position in social hierarchy, a location in the stratification system typically based on wealth and income. While in the medieval and early modern period the term 'class' was seldom used – overshadowed by more traditional notions, such as 'estates' and 'orders' – it was, nevertheless, mentioned as a generic classificatory concept, an equivalent of 'social rank' or 'stratum.' The modern usage, pioneered by Karl Marx, oscillates between this generic meaning of the main 'polar' social division, and a more specific meaning, as a type of social division emerging together with modern capitalism. The latter – the modern class based on capital ownership and employment status – was contrasted with the old social divisions ('estate' or 'order') based on the ownership of land and the accompanied status (honor). While the old 'estates' were closed and ascriptive, the new class divisions were seen as open and achievement based. It was the 'first estate' – the despised, privileged, and exclusive aristocracy – that provoked the ire of French revolutionaries.

Class in Marxism

The contemporary meaning of 'class' arose in the context of the Marxist theory of social conflict and change formulated in response to the Industrial Revolution in Britain and Western Europe or, strictly speaking, to the disruptive social consequences of the 'Great Transformation' (Polanyi, 1944). Modern sociologists, political scientists, social historians, and anthropologists made 'class' a central focus of their analysis, mainly under the influence of rising and evolving Marxism. Class was the central concept in Marxist historical materialism, referring to three theoretically interrelated analytic entities, usually organized into 'polar' (opposed) pairs: (1) the major structural socioeconomic categories differing in their relation to the key 'means of production' or the key productive resources (capital

vs labor) – sometimes referred to by Marx as *Klasse an sich*; (2) the large social groupings, the social 'carriers' of the employment relations, forming on the basis of the main ownership/employment relations (bourgeoisie vs proletariat); and finally (3) the principal collective 'social actors': class-conscious, solidarity, and organized 'social forces,' formed in the process of class struggles (ruling class vs challenging class) – seen by Marx as 'mature' *Klasse für sich*.

This multiplicity of meanings reflected the Marxist theoretical aspiration to explain the social–historical evolution of societies (the 'rules of motion of capitalist society'), and bridged the gap between structural accounts of social hierarchy on the one hand, and the 'actor-centered' accounts of social change on the other. Class became a pivotal 'bridging concept' in this attempt. Social change always started, according to Marx, within the socioeconomic 'base' of society (technology and know-how). It then articulated itself in conflicts between the main antagonistic classes. These principal class conflicts – in the case of capitalism between the bourgeoisie (capital owners–employers) and the proletariat (workers–employees) – were gradually intensifying leading to revolutionary changes.

In addition to major 'polar' or 'antagonistic' classes, Marx also distinguished some 'intermediate' and 'transient' classes bound to gradually disappear in the processes of class polarization and struggle (Table 1). The class structure of modern capitalism was thus seen not only as complex, but also as gradually simplifying and polarizing. The most developed capitalist societies were to be sharply divided into the mature ruling class (bourgeoisie) that typically controlled and managed the state, and the expanding, impoverished, and dominated – and also increasingly conscious, antagonistic, and organized – working class. This class polarization and contestation was supposed to reach its peak when the dominated class – now class-conscious, politically organized, and backed by bourgeois defectors – took over power in a revolutionary coup and completed a revolutionary reconstruction of society. Note that in this evolutionary–revolutionary cycle major classes would change from nominal categories (*Klasse an sich*) to real grouping and organized collective actors (*Klasse für sich*), while minor classes would wither away. Note also that the concept of class was ideologically 'loaded' because Marxism claimed to be not just an explanatory theory but also – and principally – a program for change, a radical recipe for social reconstruction.

Table 1 The Marxist class scheme

Classes	*Trends*
Bourgeoisie	Growing in power and organization but declining in number
Old dominant classes (aristocracies & nobilities)	Declining in number and power
New middle classes (officialdom)	Growing in number but joining the bourgeoisie
Old middle classes (petit bourgeois, craftsmen, peasant-farmers)	Declining in number and power
Working class	Growing in number, consciousness, and organization

Based on Pakulski, J., 2004. Globalising Inequalities. Allen & Unwin, Sydney.

At the end of the nineteenth century, the process of conceptual refashioning of class started in the most industrialized European societies, with the realization that class polarization was arrested, class radicalism gave way to reformism, and the large 'middle classes' are expanding, rather than shrinking. Moreover, the 'old' social divisions ('estates') had not disappeared, and the new social divisions along ethnonational (and racial) lines started to dominate popular identifications.

Thus, the concept of class started to evolve in competition with four main conceptual rivals. The first one was 'estate' or 'order' that described hierarchical 'social ranks': the nobility, the clergy, and the residual 'third estate' of peasants, traders, and burghers, as well as a new status group of 'the intelligentsia,' emerging from the *déclassé* nobility. Class also competed with the increasingly popular concepts of 'people' (nation), referring to groups sharing a similar culture and tradition, as well as 'races,' referring to social categories with physical similarities. Another conceptual competitor was an equally polar pair of concepts, 'elites vs the masses,' popularized by mainly Italian critics of Marxism (Vilfredo Pareto, Gaetano Mosca, and Roberto Michels). This competition was particularly intense in Europe. In the United States, where ethnoracial divisions were more salient than socioeconomic ones, class was overshadowed by race.

Class in the Twentieth Century

Class emerged as the dominant concept–descriptor of social inequality and conflict at the beginning of the twentieth century. There were three reasons for this triumphant ascendancy: class was embedded in an increasingly popular (mainly in Europe) Marxist theory of social conflict and change; it became part of an attractive ideology promising a happy resolution of the main 'social question'; and class mobilization became a goal of both the radical social movements (socialist, revolutionary), as well as the moderate social-reformist push (social democrats). Moreover, the Bolshevik Revolution in Russia, an event that demonstrated the ideological mobilizing potential of the class concept, enhanced the popularity of 'class,' especially among socialists.

This ascendancy, however, was accompanied by theoretical and semantic diversification. As pointed out by Ossowski (1963/1958), the meaning of 'class' diverged within three theoretical–political contexts.

Polar Classes

Most Marxists, as well as radical social democrats, advocated 'polar' class schemes that stressed class exploitation and conflict: exploiters vs exploited, rich vs poor. Thus the Bolshevik leader, Vladimir Lenin, famously defined classes as "large groups of people differing from each other by the place they occupy in a historically determined system of social production, by their relation (in most cases fixed and formulated in law) to the means of production, by their role in the social organization of labor, and, consequently, by the dimensions of the share of social wealth of which they dispose and the mode of acquiring it" (Lenin, 1919/1928: 408).

Occupational Classes

The functional theorists, by contrast, identified classes with occupational groupings. Thus defined, classes were seen as elements of social differentiation, rather than social stratification. They complemented each other, even if competing for material rewards, privileges ('rents'), and social recognition. Many contemporary scholars, such as Grusky and Sorensen (1998), follow this analytic tradition and see social classes as 'hierarchically organized occupational microcommunities.' Contemporary analysts of such occupational classes tend to stress competition between occupational classes, rather than class conflict. Studies of labor market differentiation and segmentation, as well as analyses of professionalization, often refer to such concept of class (e.g., Grusky, 2005).

Class Stratification

Finally – and perhaps most significantly – class was redefined by Max Weber and his followers as a 'market-based social stratification concept.' Weberian classes, forming modern 'social ladders,' consisted of large social groupings that shared similar types and levels of 'market endowments,' that is, property, skills, and labor power. They differed in degree of 'social formation,' that is, the degree to which class members shared mobility chances, lifestyles, and identities. The typical class structure of industrialized societies, according to Weber, consisted of four large and hierarchical 'social classes': the owner and manager class, the *petit bourgeoisie* or small owner class (mainly shopkeepers and family businessmen), the white collar (mainly clerical) class, and the manual working class. Social classes seldom gained a high level of class consciousness, identity, and organization – a view that contrasted with the Marxist belief in the inevitable evolution of the major classes into organized *Klasse für sich*. Thus, the Weberian concept(s) of class became the major element of the burgeoning field of stratification and mobility studies.

Initially, the Weberian reformulations were overshadowed by the more radical Marxist vocabularies of class. In fact, the early twentieth century marked the most dramatic period in the history of class concept. World War I, the Bolshevik Revolution, and the Great Depression radicalized national populations, thus forming receptive audiences for the Marxist concept of class in its polar and radical versions. In the highly industrialized western Europe, antagonistic class divisions, class movements, and elaborate class ideologies formed a powerful stream of turbulent 'class politics' competing with equally violent racist–nationalist politics. This resulted not only in mass radicalization, favoring the polar class schemes, but also in 'reversals of democratization,' emergence of radical dictatorships ('revolutionary dynamo states'), brutal wars, and genocides: the Soviet–Stalinist 'classicides' and the Nazi 'ethnoracial genocides.'

Proliferation, Decomposition, and Decline

The class concept reached the peak of its popularity in the 1950s–70s as the flagship concept in the social sciences and in popular discourses on social stratification and mobility. It was seen as the main element of modern social structure, and as the key element of occupational class stratification. This widening popularity accompanied the ascendancy of 'class analysis' – a type of social analysis focusing on class inequality and antagonism. In the United States, class entered popular vocabularies mainly via 'community studies,' where 'class' meant a social rank in a stratified community – a group of families sharing a similar social status or 'standing' (e.g., Warner, 1960).

The 'Golden Age' of class was in the 1960s–80s when comparative national studies of class inequality, class stratification, and class mobility reached their peak. In such studies, social inequalities were portrayed as pyramids of hierarchical occupational classes. Class mobility was measured as circulation between those class locations, while mobility barriers defined 'class closure.' Class identifications were treated as universal 'master identities'; politics in industrialized 'advanced societies' were analyzed as 'democratic class struggles'; and cultural divisions were construed in terms of 'class cultures' (e.g., Giddens, 1973; Parkin, 1979; Goldthorpe, 1980; Wright, 1978; Lipset, 1960/1981). Perhaps the best known and most frequently used was a collapsible class-stratification scheme popularized worldwide by John Goldthorpe in international comparative studies of class structure and mobility (Erikson and Goldthorpe, 1992) (**Table 2**).

The concept of 'class' was also applied – although seldom officially – to analyses of inequalities and conflicts in the Soviet-type societies. Thus Wesolowski (1978) charted class and 'strata' inequalities in Poland, while dissident scholars, such as Djilas (1957) in Yugoslavia and Konrad and Szelenyi (1979) in Hungary singled out *the intelligentsia* and the party-state *nomenklatura* (patronage list of top party-state officials)

Table 2 Goldthorpe's class scheme

Full 11-class version	*Seven-class scheme*	*Five-class scheme*	*Three-class scheme*
1. Higher Professional			
2. Lower Professional	Service class (1 + 2)	White collar (1–3)	
3a. Higher administrator			
3b. Sales & service	Sales & service (3)		Nonmanual (1–4a)
4a. Small owner/ employer			
4b. Small owner	Petty bourgeois (4a, 4b)	Petty bourgeois (4a, 4b)	
4c. Farmer	Farmer (4c)	Farm worker (4c)	Farm worker (4c)
5. Lower Technician			
6. Skilled Manual	Skilled worker (5 + 6)	Skilled worker (5 + 6)	Manual (5–7)
7a. Semi- and unskilled	Unskilled (7a)	Unskilled worker (7)	
7b. Agricultural worker	Agricultural labor (7b)

as new and exploitative state–socialist 'ruling classes' pitched against the 'working classes.'

Amid this proliferating class analyses, however, there appeared some critical voices pointing to major transformations in class structure and the declining relevance of class. The advocates of '*embourgeoisement*' suggested that spreading affluence, welfare reforms, and intense mobility lead to the formation of 'middle class' societies. The early advocates of 'industrial society,' like Ralf Dahrendorf (1959), pointed to a progressive 'decomposition' of major social classes that resulted in proliferation of intraclass divisions, expansion of the new and amorphous 'middle classes,' intense mobility, declining class identity, consciousness and solidarity, and waning industrial class conflict. The advocates of 'post-industrial' developments, like Daniel Bell (1973), in turn, stressed the declining silence of class divisions and the growing relevance of knowledge/education and 'sector location' ('social situs'). At the same time, the neo-Weberian scholars, like Giddens (1973), pointed to the variability and flexibility of 'class structuration,' and started to supplement class schemes with rival concepts, such as 'elites,' 'strata,' and ethnoracial 'underclass.' In the meantime, students of occupational attainment and class mobility (e.g., Blau and Duncan, 1967; Goldthorpe, 1980; Heath, 1981) stressed the porous nature of class boundaries and high intensity of interclass movements. Even the neo-Marxist analysts, like E.O. Wright (1978), who initially defended the Marxist class scheme, started to multiply classes (from 4 to 12), stress the multidimensionality of class structure, and admit the blurring of class divisions – changes that marked a turning point in the popularity of class and the growing convergence between 'class' and its conceptual rivals (Wright, 1996, 1997; **Table 3**).

This convergence, however, was accompanied by confusion. Thus, E.P. Thompson (1964: 9) defined class as a rather nebulous "historical phenomenon, unifying a number of disparate and seemingly unconnected events." "I do not see class as a 'structure' nor even as a 'category'" – Thompson declared – "but as something which in fact happens … when some men, as a result of common experiences (inherited or shared) feel and articulate the identity of their interests as between themselves, and against other men whose interests are different from (and usually opposed to) theirs." Class concept, in other words, started to lose consistency and clarity, and with it also its analytic utility.

The advocates of class did not give ground without a fight. The prominent class analysts were busy adapting the concept to proliferating social and cultural studies. Prominent sociologists tried to explain the fuzziness and fluidity of 'new class divisions' by pointing to changing work conditions and intense mobility (Goldthorpe), diverse patterns of 'class structuration' (Giddens), variation in class closure and class formation (Parkin), and by the emergence of altogether new classes (Poulantzas, Wright).

A vigorous defense of class as a relevant and useful concept was also undertaken by the neo-Marxist 'world system' or 'dependency' theorists, such as Immanuel Wallerstein (1974), and by the 'culturalists' like Pierre Bourdieu (1984/1979). Wallerstein and his followers (including Christopher Chase-Dunn and Daniel Chirot) argued that class divisions and conflicts should be reconceptualized within a global 'world-systemic' theoretical framework as structural world-market divisions between families of nation-states. They distinguished between internal classes (within nation-states) and global classes: capitalist 'core' (consisting of the most developed nation-states) and the underdeveloped 'periphery' (consisting of developing regions). Between them there were 'semiperipheral' societies, such as Australia and Canada, as well as noncapitalist societies of the Soviet type. Popularity of these global (world-market) class schemes faded with the collapse of Soviet-type societies and the rapid development of the industrializing nations – both contradicting the predictions of dependency theorists. Even when S.M. Lipset, the doyen of class analysis in America, abandoned his original scheme of 'class politics' and 'democratic class struggle' (Clark and Lipset, 1991), the defenders of class and class analysis were confirming its new relevance (e.g., Hout et al., 1995; Wright, 1996).

While losing its popularity among mainstream analysts, class continued to be deployed by 'global class' theorists who suggested the 'denationalization' of classes, such as the 'transnational bourgeoisie' (Robinson, 2004: 49–57). Sassen (2007: 167–170) has distinguished three such 'denationalized' classes: transnational corporate professionals and executives, top state executives, and 'an emergent class of disadvantaged or resource-poor workers and activists.'

Bourdieu's (1984, 2001)'culturalist' reconceptualization of class has opened the debate about the importance of 'cultural capital' (closely identified with education, taste, and lifestyle) and cultural domination in generating new class divisions. According to Bourdieu, diverse lifestyles reflect distinctive *habituses*, which, in turn, are organized in the process of social–cultural contest into hierarchical (in relation to 'legitimate culture') and antagonistic classes. The subordinate/working classes contest social and cultural domination of dominant/

Table 3 Wright's class scheme

		Relations to the means of production				
		Owner		*Employees*		
Number of Employees	Many	Capitalist	Expert manager	Skilled manager	Nonskilled manager	**Relation to authority**
	Few	Small employer	Expert supervisor	Skilled supervisor	Nonskilled supervisor	
	None	Petty bourgeois	Expert worker	Skilled worker	Nonskilled worker	
			Expert	*Skilled*	*Nonskilled*	
			Relations to scarce skills

ruling classes. But classes are many, and they are diverse, fuzzy, and fickle. Their composition and boundaries constantly change. Moreover, as stressed by Weininger (2005), class divisions and conflicts analyzed by Bourdieu always fuse with much older and more entrenched racial and gender divisions and conflicts. The latter cannot be separated from contemporary class antagonisms, thus generating a complex web of crosscutting hierarchical divisions.

Bourdieu's approach has not only popularized – but also further diluted – the concept of class. It now applies to any socially recognized division: market-occupational, cultural-lifestyle, status-consumption, etc. – and it acquired gender and racial 'dimensions' that further complicate class analysis. Alas, the initial enthusiasm greeting Bourdieu's analyses started to fade when it became apparent that his 'flexible and inclusive' class scheme cannot be operationalized in a clear way.

The Proliferation of Classes or the 'Death of Class'?

As far as the concept of class is concerned, the current (2014) state of affairs is variously characterized as either an 'adaptive proliferation' or as the 'death of class,' a progressive waning of the class concept and its disappearance from academic and popular vocabularies.

The prominent neo-Marxist scholar E.O. Wright (Wisconsin–Madison), together with and Richard Breen (Oxford), neo-Ricardian analysts, such as Aage Sorensen (Harvard), and the neo-Durkheimian David Grusky (Stanford), have recently suggested that the concept of class and the accompanying class analysis do not decline in relevance, but simply diversify and adapt to new global and postindustrial conditions (Wright, 2005). Consequently, what the term 'class' means and denotes depends on the social-historical and theoretical contexts within which the concept is embedded. And these contexts continue to multiply. For the British neo-Weberian, Anthony Giddens (2006: 300), class is "a large scale grouping of people who share common economic resources, which strongly influence the type of life they are able to lead. Ownership of wealth, together with occupation, are the chief bases of class differences." For an American ('analytic') neo-Marxist, Wright (2005: 16–21), class refers to structural category of people located in similar (unequal and exploitative) ownership/work relations. For a follower of neoclassical economics, Sorensen (2005: 119–152), class denotes a category of people who extract similar economic 'rents,' that is, similar privileges and disadvantages. For a neo-Durkheimian, David Grusky (2005: 51–81), class is identical with a cohesive occupational group community and it forms the main element of contemporary social stratification. Followers of Bourdieu, by contrast, see classes as blurred but antagonistic social-cultural groupings, and they draw complex 'class maps' combining economic and cultural capitals. Students of globalization add to the widening gallery of competing class concepts 'transnational classes.' Structural and hierarchical delineations of 'classes' compete with those that denote a capacity for solidary collective action. You can pick your class concept and theoretical–analytic framework – whichever you find relevant and attractive.

Other scholars, the 'class skeptics,' claim that class is 'dying' and class analysis has been losing its relevance and utility (e.g., Beck, 1992; Clark et al., 1993; Pakulski and Waters, 1996; Clark and Lipset, 1991, 2001). This does not mark the end of social hierarchy, but a change in the forms of this hierarchy, division, and conflict. The old divisions – for which the concept of class was originally forged – have been decomposing, the accompanying class identities decline, and the lifestyles and politics associated with those divisions have withered away. Class inequalities, in other words, are gradually replaced by fluid and diverse – although often steep – 'classless inequalities.' Class is no longer a useful analytic concept-tool, especially in studies of the contemporary stratification resembling a 'status bazaar.' Contemporary cultures diversify into fluid subcultures and they spawn cultural 'omnivores' whose tastes and lifestyles defy Bourdiesque *habituses*. Politics also lose their class 'moorings.' Class–voter–party dealignment has resulted in the rapid decline of 'class identification' and 'class voting.' This is accompanied by a gradual withering away of 'class issues,' 'class parties,' and 'class politics.' They are replaced by 'celebrity' issues, risk concerns, cartel-type parties, and populist politics. Patterns of political association and action detach themselves from the old class-related ideological packages. So do the issue–agendas of social movements and mass parties. Both abandon class issues, vocabularies, and ideological programs (e.g., Beck, 1992; Giddens, 2000; Pakulski, 2005). Consequently, the major developments in the last three decades – the crisis and collapse of the Soviet Union, the unification of Europe, the ascendancy of market liberalism, the mobilization of powerful 'new' movements, (left-libertarian and right populist), the eruptions of 'terror-containment wars,' and the trans-Atlantic Great Recession – all defy analysis and explanation in class terms.

The major public and academic sources today define 'class' in most general terms, often detached from theoretical contexts. Thus the *Princeton Web Encyclopedia – Glossary* (2013) defines class as "people having the same social, economic, or educational status," while *Wikipedia* (2013) – an increasingly popular source – sees "**Social class** (or simply 'class'), as in a **class society**, [as] a set of concepts in the social sciences and political theory centered on models of social stratification in which people are grouped into a set of hierarchical social categories, the most common being the upper, middle, and lower classes." Moreover, the popularity of the concept continues to decline. While class dominated as a topic and referent in sociological journals in the 1970s and 1980s, it was mentioned in only 15% of British Sociological Association (BSA) articles at the turn of the century, and in only 8% of articles in *Sociology* in 2010 (Payne, 2011).

Class Size

Diane W Schanzenbach, Northwestern University, Evanston, IL, USA

Abstract

This article summarizes the literature on the impact of class size on student achievement. Following a brief discussion of the theory linking class size to student outcomes, I review the experimental and quasi-experimental evidence on the impact of class size. Research using a variety of approaches across a variety of settings indicates that class size is an important factor in student outcomes.

Introduction

Average class size in primary grades varies widely across countries, from over 30 in Chile and Korea to under 17 in Luxembourg, Greece, and the Russian Federation (OECD, 2010). Simple correlations between class size and student outcomes without accounting for the selection process of students to class size may be extremely misleading, as they may provide a biased estimate of the true impact of class size on student outcomes. This article begins with an overview of the theory linking class size to student outcomes, followed by a discussion of the empirical strategies used in research to identify the causal impact of class size on student achievement. It concludes with a review the empirical literature on class-size reduction focusing on studies using experimental and quasi-experimental techniques because these rely on the most credible strategies for identifying the cause-and-effect relationship between class size and student achievement.

Class Size as an Educational Input

Theories linking smaller class sizes to better student achievement generally posit that the relationship is mediated through increased time on task, the use of more effective instructional techniques such as individualized instruction, or both. None of the well-identified research studies described below are able to trace out the mechanisms through which smaller class sizes produce higher student achievement, and there is substantial uncertainty about the mechanism at work (Blatchford et al., 1998, 2002). Nonetheless, there is some research evidence suggesting that teachers spend less time on classroom management and discipline and more time on instruction activities in smaller classes (Bourke, 1986; Pate-Bain et al., 1992; Blatchford and Mortimore, 1994; Zahorik et al., 2003; Blatchford and Martin, 1998). In addition, the use and size of classroom groupings appears to be an important mechanism through which class size affects learning (Blatchford et al., 2001).

Lazear (2001) formalizes a useful theory of class size in which any given student is behaving in class at a given moment with probability p, and misbehaving with probability $(1\text{-}p)$. With n children in the classroom, p^n is the probability that the entire class is behaving at a given time (assuming that p is independent across children). Assuming a constant disruption rate, fewer students in class – holding total time in class constant – implies more time on task. As a result, the impact of a reduction in class size is a function of both the size of the class and also the behavior level of students. The theory therefore predicts that class-size effects will be larger for classes with more poorly behaved students.

Studying the Impact of Class Size

A naïve approach to modeling the relationship between student achievement and class size would be to estimate a regression analysis where a student's outcomes are a function of school-level inputs (such as class size and teacher quality), family inputs (such as income and parental education) plus an unexplained error term. Using such an approach, a negative estimated coefficient on class size indicates that student achievement tends to decline as class size increases.

The drawback of estimating such a model is that the estimated coefficient on class size will not reflect the causal impact of smaller class size if a student's class size is systematically related to other factors that determine achievement. If these other factors are not controlled, then the equation will suffer from omitted variables bias and the estimated coefficient may be severely misstated. For example, if weaker students are assigned to small classes in order to remediate their achievement, but if the researcher cannot adequately account for this information, then the estimated impact of school resources will be biased (Boozer and Rouse, 2001). In general, studies that control for observable factors but do not have a credible explanation for why students experience different class sizes are unlikely to yield reliable estimates of the impacts of class size.

The importance of using a research design that can estimate the causal impact of class size has long been acknowledged in the literature. In their influential meta-analysis of the research on class size and achievement, Glass and Smith (1979) conclude that there is a clear, strong relationship between class size and achievement, and that the relationship is "strongest in well-controlled studies in which pupils were randomly assigned to classes of different sizes." Subsequent literature reviews by Hanushek (1986, 1997) came to the opposite conclusion that the literature did not find a 'strong or consistent relationship' between student performance and class size. The Hanushek reviews have been sharply criticized both for the quality of studies included and for the manner in which they were aggregated (Krueger, 2003; Hedges et al., 1994). In

particular, many of the underlying studies included in the surveys employed research designs that would not allow researchers to isolate the causal effects of class size, but were nonetheless given substantial weight. Below, I limit the article to work that uses experimental or quasi-experimental research designs such as policy changes to identify the impact of class size.

Experimental Research

The most influential studies of class-size reduction are based on data from Project STAR (Student-Teacher Achievement Ratio), a large-scale randomized experiment in the U.S. state of Tennessee conducted from 1985 to 1989. In it, students were randomly assigned to attend one of three treatment types: a small-size class (target of 13–17 students), a regular-size class (target of 22–25 students), or a regular-size class with a full-time teacher's aide. Importantly, teachers were also randomly assigned to class types. The experiment took place in 79 public schools across a variety of geographic locations (inner-city, suburban, and rural; predominantly low-income and middle-class) for a single cohort of students in kindergarten through third grade. More than 11 500 students and 1300 teachers took part in the experiment. Students were randomly assigned within schools (or, more precisely, school interacted with the first year a student entered the treated cohort which was for most students either kindergarten or first grade). By design, students were to remain in the same randomly assigned class-type from kindergarten through the end of third grade. In practice, there were several major sources of deviation from this model such as nonrandom switches across class types, but the findings of the experiment have been shown to be robust to careful controls for these deviations (see Krueger, 1999).

Many researchers have shown that students randomly assigned to a small class perform 0.15–0.20 standard deviations higher on math and reading achievement tests compared with students in their school and grade who were randomly assigned to a regular-size class (Word et al. 1990; Krueger, 1999; Krueger and Whitmore, 2001; Schanzenbach, 2007). When the results are disaggregated by student characteristics, it appears that African-American students and low-income students benefit more from small classes than the overall population.

In fourth grade, the class-size reduction experiment concluded and all students were returned to regular-sized classes. Since participants have been tracked through approximately age 30, a good deal is known about long-term impacts of class-size reduction in the early grades. Overall, there is a persistent positive impact of small-class assignment that is, statistically significant (or borderline significant) through eighth grade, but the magnitude of the gain is one-third to one-half the size that was observed while the students were enrolled in the experimental classes (see Krueger and Whitmore, 2001). There is also some evidence of improvements in nonacademic outcomes during the teenage years, such as reduced criminal behavior and teen pregnancy (Krueger and Whitmore, 2002). Finn et al. (2005) find that small-class students more likely to graduate from high school. Students who had been randomly assigned to a small class were more likely to take a college-entrance exam in high school (Krueger and Whitmore, 2001).

Using information on college enrollment, new studies have shown that small-class attendance increases the rate of postsecondary attendance by between 1.8 (Chetty et al., 2011) and 2.7 percentage points (Dynarski et al., 2013), and increases the probability of earning a college degree by 1.6 percentage points. Small-class students have better outcomes across an index measured in early adulthood and including measures such as whether they are married, homeowners, have retirement savings, earnings, and neighborhood quality. Impacts on earnings from age 25–27 are not statistically significantly different from zero, but have a wide confidence interval. Across all dimensions, the long-term impacts have generally been found to be the strongest among disadvantaged children.

An important concern for any experimental results is whether the results may be generalized to other settings. Along many measures, Tennessee in the mid-1980s looks similar to other places that might be interested in implementing a class-size reduction policy, so it would be reasonable to expect similar effects as those in the experiment. However, compared with the United States overall, Tennessee has lower levels of educational inputs, such as education spending and teachers' educational attainment. If adding resources has a greater impact when baseline levels are already low, it might suggest that schools with higher levels of spending could experience a smaller impact of class-size reduction (Schanzenbach, 2007).

Quasi-Experimental Research

Because true randomized experiments are rare, researchers must also look for quasi-experimental approaches that allow isolation of the causal impact of class-size reduction. The most famous quasi-experimental approach to studying class-size reduction comes from Angrist and Lavy's (1999) use of a strict maximum class size rule in Israel and a regression discontinuity (RD) approach. In Israel, Maimonides' Rule dictates that no more than 40 students shall be in one class. As a result, the maximum class size faced by a student drop changes dramatically when enrollment is close to multiples of 40. For example, if a grade has 80 students, then a school could offer only 2 classrooms, with 40 students in each. If a grade has 81 students, however, in order to abide by the maximum class-size rule the school must offer (at least) 3 classrooms and maximum average class size falls to 27 students. In practice, some schools add an additional classroom prior to hitting the 40-student cap. Nonetheless the maximum class-size rule is a good predictor of actual class sizes, and can be used as an instrumental variable to isolate the causal impact of class size on student achievement. Using local variation around the enrollment sizes that are multiples of 40 students, Angrist and Lavy find strong improvements overall in both math and reading scores, of a magnitude that is consistent with Project STAR's experimental results. Consistent with the experiment results, they also find larger improvements among disadvantaged students.

There have been several subsequent papers that have identified the impact of smaller class sizes using maximum class size rules in other settings. Most recently, Fredriksson et al. (2013) evaluate the long-term impact of class size using data from Sweden and measuring class sizes among students between ages 10 and 13 who were facing a maximum class size rule of 30 students. At age 13, students who were in smaller classes had higher cognitive and noncognitive skills. In adulthood (measured between ages 27 and 42), students in smaller classes had higher levels of completed education, wages, and earnings. In addition, Urquiola (2006) uses a similar regression discontinuity approach in Bolivia and finds that a one standard-deviation reduction in class size (about 8 students in his data) improves test score performance by 0.2–0.3 standard deviations. Browning and Heinesen (2007) find similar results on data from Denmark, even though average class size is much smaller in their study (20 pupils per classroom, compared to 31 students in Angrist and Lavy's Israeli data). Urquiola and Verhoogen (2009) provide a cautionary tale about possible endogenous responses of schools to class-size caps, and show that in Chilean data that these endogenous responses of schools lead to violations of the assumptions of the RD design.

Another quasi-experimental approach was used to evaluate Wisconsin's targeted class-size reduction program called the Student Achievement Guarantee in Education (SAGE) program (Molnar et al., 1999). In SAGE, high-poverty school districts could apply to implement a pupil–teacher ratio of 15 to 1 in grades K-3. While most participating schools reduced class sizes, some schools chose to attain the target pupil–teacher ratio using two-teacher teams in classes of 30 students. Test scores of first graders in SAGE schools were higher in math, reading, and language arts compared with scores of first graders in selected comparison schools in the same districts, which had average pupil–teacher ratios of 22.4 to 24.5.

Another quasi-experimental approach is to use variation in enrollment that is driven by random fluctuations in cohort sizes across different years. Hoxby (2000) takes this approach using data from the U.S. state of Connecticut. After removing any preexisting trends in enrollment that might signify that a school district is waning or booming, the effect of class size is identified by the variation in cohort size that reflects a temporary random shock in population size that may have been caused by an unusually small (or large) birth rate in a given year. Using this approach, there is no statistically significant positive effect of smaller class size, and the estimates have the statistical precision to rule out an effect as large as about one-fifth the size found in Project STAR. The discrepancy between these results and those of other well-identified experimental and quasi-experimental studies remains a puzzle.

Relatively few well-identified studies have estimated the impact of class-size reductions in later grades. A notable exception is Dee and West (2011), which uses a fixed-effect approach to estimate within-student and within-teacher class-size effects. The study finds that small classes improve several measures of students' engagement in school. Furthermore, the fixed effects estimates are substantially larger than the ordinary least squares regression results, which is consistent with weaker students being assigned to smaller classes.

Statewide Policy-Induced Variation

Based in part on the research evidence on the impact of class-size reduction, several U.S. states including California, Texas, and Florida have implemented class-size caps. The most widely studied of the state policies was California's 1996 adoption of a law that gave strong monetary incentives to schools to reduce class size in grades K-3 to 20 or fewer students. The take-up of the policy was nearly universal within a short period of time, so there was very little scope to evaluate its impact. In addition, test scores are only available starting in grade 4, so any evaluation of the policy was forced to use subsequent test scores instead of scores during the year that the reduced class size was experienced. Evaluations suggest positive impacts on achievement that were probably somewhat offset because many inexperienced teachers had to be hired to staff the new classrooms (Jepsen and Rivkin, 2009; Unlu, 2005).

Discussion

The bulk of the research using credible identification of the impacts of class-size reduction suggests that reducing class size in the early grades improves both short- and long-run student outcomes. In addition, benefits appear to be larger for disadvantaged groups such as African-American students and children from low socioeconomic status families. There are many important research questions that have not been adequately addressed in the literature. For example, while class-size effects across a variety of studies appear to be stable and roughly linear in the range of 12–40 students, little is known about the potential effects of class size outside of this range. Similarly, little is known about the impact of class size on students older than elementary school.

An important question that policy makers must ask prior to embarking on class-size reduction is whether the projected benefits outweigh the costs. A cost–benefit study of Project STAR found that the overall benefits outweighed the costs (Krueger and Whitmore, 2001). The answer in other cases may depend on context, such as what is the level and distribution of current resources, can additional teachers of comparable quality be hired, and what is the best alternate use of available resources.

This article is a revision of the previous edition article by P. Saunders, volume 3, pp. 1933–1938, © 2001, Elsevier Ltd.

Abstract

The labor market of contemporary societies is rife with various types of 'classes' that impede the free flow of labor by restricting entry to those who have the requisite degrees, certificates, memberships, or capital. These classes take the form, for example, of occupations (e.g., economist, carpenter), aggregates of occupations (e.g., manager, farmer), or groups that represent competing factors of production (e.g., workers, capitalists). The purpose of this article is to review the conceptual foundation of class models and to introduce some of the research based on a class analysis of inequality.

Given the complexity of contemporary inequality, one might expect most scholars to adopt a multidimensional approach to characterizing it, an approach that might begin by specifying the multivariate 'inequality space' defined by the distribution of income, power, honor, and other valued resources. This instinct, however reasonable it might seem, has not in fact been the dominant one in the field. It instead remains conventional, especially among sociologists, to describe stratification systems in terms of discrete classes or strata whose members are presumed to have similar levels or types of assets. In the most extreme versions of this approach, the resulting classes are assumed to be real entities that preexist the distribution of assets, and many scholars therefore refer to the 'effects' of class location on the assets that their incumbents control.

The claim that inequality takes on a 'class form' is one of the distinctively sociological contributions to inequality measurement and stands as the main alternative to approaches that either focus exclusively on income inequality or analyze the many dimensions of inequality independently and separately. The main advantage of class-based measurement, as argued by some sociologists, is that conventional class categories (e.g., professional, manager, clerk, craft worker, laborer, farmer) are institutionalized within the labor market and are accordingly more than purely nominal or statistical constructions. The labor market, far from being a seamless and continuous distribution of incomes, is instead understood as a deeply lumpy entity, with such lumpiness mainly taking the form of institutionalized groups (i.e., 'classes') that constitute prepackaged combinations of such valued goods as income, power, or honor.

Within sociology, the implicit critique, then, of income-based approaches rests not so much on the argument that the income distribution is just one of many distributions of interest (i.e., multidimensionalism), but rather on the argument that measurement strategies based on the income distribution alone impose an excessively abstract, analytic, and statistical lens on a social world that has much institutionalized structure to it. This structure takes the tripartite form of a set of social classes that are privileged under capitalist labor markets (e.g., capitalists, professionals, managers), a set of social classes that are less privileged under advanced capitalism (e.g., routine nonmanuals, craft workers, operatives), and an 'underclass' that stands largely outside the labor market and is accordingly deeply disadvantaged in market systems. The rise of class models should therefore be understood as a distinctively sociological reaction to the individualism of the income paradigm and other unidimensional approaches to measuring inequality.

The foregoing account, which is a largely consensual rendition of the rationale for social class measurement, nonetheless conceals much internal debate within the field on how best to identify and characterize the boundaries dividing the population into classes. It is useful to review the three main phases in which these debates have played out.

Structuralist Phase (*c.*1945–85)

The class models of the postwar period rested implicitly or explicitly on the assumption that classes are bundles of endowments (e.g., education levels), working conditions (e.g., amount of autonomy), and reward packages (e.g., income) that tend to cohere together (Giddens, 1973; Parkin, 1979). The middle class of 'craft workers,' for example, comprises individuals with moderate educational investments (i.e., secondary school credentials), considerable occupation-specific investments in human capital (i.e., on-the-job training), average income coupled with substantial job security (at least until deindustrialization), middling social honor and prestige, quite limited authority and autonomy on the job, and comparatively good health outcomes (by virtue of union-sponsored health benefits and regulation of working conditions). By contrast, the underclass may be understood as comprising a rather different package of conditions, a package that combines minimal educational investments (i.e., secondary school dropouts), limited opportunities for on-the-job training, intermittent labor force participation and low income, virtually no opportunities for authority or autonomy on the job (during those brief bouts of employment), relatively poor health (by virtue of lifestyle choices and inadequate health care), and much social denigration and exclusion. The other classes appearing in conventional class schemes (e.g., professional, managerial, routine nonmanual) may likewise be understood as particular combinations of 'scores' on the most important assets or resources.

For the purposes of illustration, consider a simplified case in which the multidimensional 'inequality space' comprises only three individual-level variables (e.g., education, autonomy, income), thus allowing the class hypothesis to be readily

graphed. Additionally, assume that the class structure can be represented by six classes (e.g., professional, managerial, sales and clerical, craft, laborer, farm), signified in Figure 1 by six different symbols (dark squares, light squares, dark circles, etc.). As shown in this figure, the two main claims underlying the class hypothesis are that (1) the structural conditions of interest tend to cluster together into characteristic packages, and (2) these packages of conditions correspond to occupational or employment groupings. For structuralists, the inequality space is presumed to have a relatively low dimensionality, indeed a dimensionality neither more nor less than the number of postulated classes. The individuals falling within the classes constituting this scheme will accordingly have endowments, working conditions, and reward packages that are close to the averages prevailing for their classes. Moreover, even when individual scores deviate from class averages, the conventional class-analytic assumption (albeit largely untested) is that the contextual effect of the class is dominant and overcomes any such individual-level deviations. For example, a full professor who lacks a PhD is presumably just as marketable as a fully credentialed (but otherwise comparable) full professor, precisely because membership in the professorial class is a master status that tends to dominate all others.

The postwar period also was notable for a flourishing of gradational measurement approaches that again treated occupations as the fundamental units of analysis but assumed that such occupations may be ordered into a unidimensional socioeconomic or prestige scale (e.g., Treiman, 1976; Goldthorpe and Hope, 1972). In Figure 1, it is assumed that the class structure cannot be understood in simple gradational terms, meaning that at least some classes were formed by combining high values on one dimension with low values on another. It is possible, however, that the structural conditions of interest tend to covary linearly, thus generating a class structure of the very simple type represented in Figure 2. In a regime of this sort, inequality becomes rather stark (i.e., crystallized), as privilege on one dimension (e.g., autonomy) implies very

Figure 1 Class regime.

Figure 2 Gradational regime.

reliably privilege on another (e.g., income). There should accordingly be much interest in determining whether inequality indeed takes this form. Unfortunately, inequality scholars of the postwar period did not typically test the crystallization assumption, but rather simply assumed that it held and proceeded to develop socioeconomic scales that treated education and income as the main dimensions of interest (and ranked occupations by averaging scores on these two dimensions).

It may be noted that many neo-Marxian scholars during this period also deviated from a strict multidimensional stance by nominating particular dimensions as being theoretically crucial and hence the appropriate basis upon which social classes might be defined. There are nearly as many claims of this sort as there are dimensions of inequality. To be sure, Marx is most commonly criticized for placing "almost exclusive emphasis on economic factors as determinants of social class" (Lipset, 1968), but in fact much of what passed for stratification theorizing during this period amounted to reductionism of some kind, albeit often an expanded version of reductionism in which two or three dimensions were nominated as especially crucial. When a reductionist position is adopted, the rationale for a class model is not typically that classes are coherent packages of conditions (as represented in Figure 1), but rather that the nominated dimension or dimensions are crucial in defining interests and will accordingly come to be the main sources of social action. The classic Marxian model, for example, has workers ultimately appreciating that their status as workers (i.e., nonowners) defines their interests.

Culturalist Phase (*c.*1985–95)

In the mid-1980s, Bourdieu (1984) and other sociologists (esp. Wilson, 1978) sought to develop a culturalist rationale for class models, a rationale that rested on the claim that classes are not merely constellations of structural conditions (e.g., working conditions, rewards) but are also socially closed groupings in

which distinctive cultures emerge and come to influence attitudes, behaviors, or even preferences of class members. Throughout this period, many sociologists continued to work with more narrowly structuralist definitions of class (e.g., Wright, 1984; Erikson and Goldthorpe, 1992), but Bourdieu (1984) and Wilson (1978) were instrumental in pressing the claim that class-specific cultures are a defining feature of inequality systems (also, Lareau, 2003).

The two main forms of closure that serve to generate class-specific cultures are residential segregation (e.g., urban ghettos) and workplace segregation (e.g., occupational associations). As Wilson notes, members of the underclass live in urban ghettos that are spatially isolated from mainstream culture, thus allowing a distinctively oppositional culture to emerge and reproduce itself. The effects of residential segregation operate, by contrast, in more attenuated form for other social classes; after all, residential communities map only imperfectly onto class categories (i.e., the demise of the 'company town'), and social interaction within contemporary residential communities is in any event quite superficial and cannot be counted upon to generate much in the way of meaningful culture. If distinctive cultures emerge outside the underclass, they do so principally through the tendency for members of the same occupation to interact disproportionately with one another in the workplace and in leisure activities. In accounting, for example, for the humanist, antimaterialist, and otherwise left-leaning culture and lifestyle of sociologists, class analysts would stress the forces of social closure within the workplace, especially the liberalizing effects of (1) lengthy professional training and socialization into the 'sociological worldview' and (2) subsequent interaction in the workplace with predominantly liberal colleagues.

When occupations or classes are allowed to have cultures in this fashion, one naturally wishes to better understand the content of those cultures and, in particular, the relationship between such content and the structural conditions (i.e., endowments, outcomes, institutional setting) that a class or occupational situation implies. At one extreme, class cultures may be understood as nothing more than 'rules of thumb' that encode optimizing behavioral responses to prevailing institutional conditions, rules that allow class members to forgo optimizing calculations themselves, and rely instead on cultural prescriptions that provide reliable and economical shortcuts to the right decision. For example, Breen and Goldthorpe (1997) argue that working-class culture is disparaging of educational investments not because of some maladaptive oppositional culture, but because such investments expose the working class (more so than other classes) to a real risk of downward mobility. In most cases, working-class children lack insurance in the form of substantial family income or wealth, meaning that they cannot easily recover from an educational investment gone awry (i.e., dropping out); and those who nonetheless undertake such an investment therefore face the real possibility of substantial downward mobility. The emergence, then, of a working-class culture that regards educational investments as frivolous may be understood as encoding that conclusion and thus allowing working-class children to undertake optimizing behaviors without explicitly engaging in decision tree calculations. The behaviors that a 'rule of thumb' culture encourages are, then, deeply adaptive because they take into account the endowments and institutional realities that class situations encompass (see Morgan, 2008).

The foregoing example may be understood as one in which a class-specific culture instructs recipients about appropriate (i.e., optimizing) means for achieving ends that are widely pursued by *all* classes. Indeed, the prior 'rule of thumb' account assumes that members of the working class share the conventional interest in maximizing labor market outcomes, with their class-specific culture merely instructing them about the approach that is best pursued in achieving that conventional objective. At the other extreme, one finds class-analytic formulations that represent class cultures as more overarching worldviews, ones that instruct not merely about the proper means to achieve ends but additionally about the proper valuation of the ends themselves. For example, some class cultures (e.g., aristocratic ones) place an especially high valuation on leisure, with market work disparaged as 'common' or 'polluting' (see Veblen, 2008). This orientation presumably translates into a high reservation wage within the aristocratic class. Similarly, 'oppositional cultures' within the underclass may be understood as worldviews that place an especially high valuation on preserving respect and dignity for class members, with of course the further prescription that these ends are best achieved by (1) withdrawing from and opposing conventional mainstream pursuits, (2) representing conventional mobility mechanisms (e.g., higher education) as tailor-made for the middle class and, by contrast, unworkable for the underclass, and (3) pursuing dignity and respect through other means, most notably total withdrawal from and disparagement of mainstream pursuits. This is a culture that advocates that respect and dignity deserve an especially prominent place in the utility function and that further specifies how those ends might be achieved.

It should by now be clear that sociologists operating within the class-analytic tradition have adopted very strong assumptions about how inequality and poverty are structured. As noted, intrinsic to the class concept are such claims as (1) the space of outcomes and capabilities has a (low) dimensionality equaling the number of social classes, (2) the class locations of individuals become master statuses that dominate (or at least supplement) the effects of individual-level endowments, and (3) such class locations are socially closed and come to be associated with adaptive or maladaptive cultures. These claims, although frequently made, have not typically been explicity tested.

Postmodernist Phase (*c.*1995–Present Day)

The third phase of conceptual work within sociology has been marked, however, by an increased willingness to challenge the assumptions underlying the class-analytic status quo. Over the last two decades, such criticisms of the class-analytic enterprise have escalated, with many postmodernist scholars now feeling sufficiently emboldened to argue that the concept of class should be abandoned altogether. Although the postmodern literature is notoriously fragmented, the variant of postmodernism that is most relevant here proceeds from the assumption that the labor movement is rooted in the old and

Figure 3 Disorganized inequality.

increasingly irrelevant conflicts of industrial capitalism, that political parties have abandoned class-based platforms in favor of those oriented toward values and lifestyles, and that class-based identities accordingly become ever weaker and more attenuated (see Hout and Laurison, 2014). The resulting 'individualization of inequality' (e.g., see Pakulski and Waters, 2008) implies that lifestyles and consumption practices are becoming decoupled from work identities as well as other status group memberships. The stratification system may be regarded, then, as a 'status bizarre' (Pakulski and Waters, 2008) in which identities are actively constructed as individuals select and are shaped by their multiple statuses.

This hypothesis, which is represented in extreme form by **Figure 3**, may well prove to be premature (but see Jonsson et al., 2011; Weeden and Grusky, 2012). Moreover, even if lifestyles and life chances are truly decoupling from economic class, this ought not be misunderstood as a more general decline in inequality per se. The brute facts of inequality will still be with us even if social classes of the conventional form are weakening. Most obviously, income inequality is clearly on the rise (e.g., Atkinson et al., 2011), while other forms of inequality show no signs of withering away. The postmodernist hypothesis speaks, then, to the way in which inequality is organized as opposed to the overall amount of such inequality.

The 'Class Effect' Rationale

We have to this point represented the class principle as a hypothesis about the clustering of observations in the inequality space. As an alternative motivation for the class hypothesis, it is sometimes claimed that classes are social contexts that affect attitudes, behavior, and individual action of many kinds. When this motivation is adopted, classes are not typically construed as information-rich social containers that capture many life conditions of interest, but rather as analytic categories that single out a particular social context that is presumed to be very consequential in defining interests. Under such a formulation, a class analyst will therefore typically nominate a single variable (e.g., authority, ownership) as especially useful in understanding the sources of social behavior, with the class categories then defined so as to capture differences across workers on that underlying variable of presumed consequence. The Marxian model, for example, famously embodies the claim that classes are best defined in terms of employment status alone (i.e., employed, self-employed), with the rationale for this definition being that employment status putatively defines interests and hence attitudes and behavior (e.g., Marx, [1894]1972). In contemporary labor markets, the class of employed workers is of course very heterogeneous, thus motivating class analysts to introduce further distinctions within that class that are presumed to be consequential in defining interests and action. There is a profusion of such contemporary class models on offer (e.g., Wright, 2005).

When a class model is motivated in terms of presumed class effects, it is important to establish that such effects are indeed truly causal. If, for example, one finds that seeming differences in the politics of professionals, managers, craft workers, and other social classes disappear when income is controlled, then presumably one can only refer to an income effect on politics, not a true class effect. Why might net effects of class be detected even with rigorous controls? In addressing this question, what must first be stressed is that, even when classes are defined in terms of a single analytic variable (e.g., form of regulation of employment), they are nonetheless often organic packages of conditions; and the constituents of these packages may combine and interact in ways that lead to an emergent logic of the situation (often expressed via a 'class culture'). The underclass, for instance, may be understood as a combination of negative conditions (e.g., intermittent labor force participation, limited education, low income) that, taken together, engender a sense of futility, despondency, or learned helplessness that is more profound than what would be expected from a model that simply allows for independent effects of each constituent class condition. To be sure, a committed reductionist might counter that one merely needs to include the appropriate set of interactions between the constituent variables, but insofar as classes define the relevant packages of interacting conditions this caveat just becomes an unduly complicated way of sidestepping the reality of classes.

Whatever the mechanism that underlies class effects, the common assumption is that classes are meaningful social contexts, just as neighborhoods are likewise understood within the 'neighborhood effects' literature as meaningful social contexts. These contexts are expected in both cases to have causal effects that are not reducible to mere selective processes. Again, we have to stress that such a 'class effects' rationale for class models is best treated as a hypothesis, as there is little in the way of substantiating evidence at this point (cf Weeden and Grusky, 2005).

Conclusions

Over the long history of class analysis, the class concept has been motivated in two main ways, either by (1) claiming that

the inequality space has a (low) dimensionality equaling the number of social classes or (2) claiming that the class locations of individuals have a true causal effect on behaviors or attitudes of interest. The foregoing claims have been unstated articles of faith among class analysts in particular and sociologists more generally. In this sense, class analysts have behaved rather like stereotypical economists, the latter frequently being criticized (and parodied) for their willingness to assume most anything provided that it leads to an elegant model.

Abstract

The notion of 'classical archaeology' is of relatively recent origins in the vocabulary of the humanities. Its common usage dates to the second half of the nineteenth century, when archaeology, a newly formed university discipline, sought its place within the broader intellectual framework of the sciences of antiquity. Seen as the foundation of occidental history, classical archaeology has its roots in the passion of Renaissance 'antiquarian' collectors of Greco-Roman works of art. With the Enlightenment came a remarkable appreciation of the history of plastic forms in antiquity (Winckelmann), as well as an increased awareness of the technical achievements of the past (Caylus). By the nineteenth century, classical archaeology had begun to distance itself from collections and from the social milieu of collecting, advocating instead the necessity of observing finds in the field, and of recognizing them as coherent wholes open to rigorous analysis. It was thus a development of archaeology writ large, a universal discipline bearing on all epochs and regions of the world, which cast light on the specificity of classical archaeology. Out of this confrontation classical archaeology has emerged today as a fully-fledged branch of archaeology, based equally on written sources and on the methods of orientalist and prehistoric research.

The notion of 'classical archaeology' is of relatively recent origins in the vocabulary of the humanities. Its common usage dates to the second half of the nineteenth century, when archaeology, a newly formed university discipline, sought its place within the broader intellectual framework of the sciences of antiquity. Seen as the foundation of occidental history, classical archaeology has its roots in the passion of Renaissance 'antiquarian' collectors of Greco-Roman works of art. With the Enlightenment came a remarkable appreciation of the history of plastic forms in antiquity (Winckelmann), as well as an increased awareness of the technical achievements of the past (Caylus). By the nineteenth century, classical archaeology had begun to distance itself from collections and from the social milieu of collecting, advocating instead the necessity of observing finds in the field, and of recognizing them as coherent wholes open to rigorous analysis. It was thus a development of archaeology writ large, a universal discipline bearing on all epochs and regions of the world, which cast light on the specificity of classical archaeology. Out of this confrontation classical archaeology has emerged today as a fully-fledged branch of archaeology, based equally on written sources and on the methods of orientalist and prehistoric research.

The notion of 'classical archaeology' is of relatively recent origins in the vocabulary of the humanities. Its common usage dates to the second half of the nineteenth century, when archaeology, a newly formed university discipline, sought its place within the broader intellectual framework of the sciences of antiquity, the *Altertumswissenschaft* of German scholarship. For knowledge of antiquity to be scientific, it had to encompass all the creations of human genius. Thus, just as philology had emancipated itself from theology, so was archaeology to free itself from philology in order to constitute, together with the latter and with ancient history, the third pillar of *Altertumswissenschaft*. This disciplinary triangle effectively constitutes the foundations of the modern conception of the classical past—that is, the past of the Greco-Roman world.

The Definition of Classical Archaeology

Such a definition of classicism is quite evidently arbitrary. It rests on a very specific and thoroughly European experience of antiquity, in which Greco-Roman literature and its concepts are overwhelmingly privileged. In specifying the chronological and geographical boundaries of the classical world, nineteenth century historians and archaeologists have confirmed a spatio–temporal distinction already initiated during antiquity, and notably in the Alexandrian golden age of the third and second centuries BC. Following this definition, the classical world effectively begins with the dispersal of the Greeks in the Mediterranean during the eighth century BC, and ends with the fall of the occidental Roman empire in 476 AD. In terms of its geographical extension, the classical world reaches as far as the farthest expansion of the Roman empire, at the end of the first century AD.

As can be seen, this mode of historical representation clearly focuses on the Mediterranean as the zone of contact between Europe, Africa and Asia. But where does this Mediterranean space actually ends? Is it somewhere in the vast European plains? On the shores of the Black Sea? At the foot of the mountain ranges bordering Anatolia or Africa? According to their readings of both the classical sources and the surrounding landscapes, experts have drawn different boundaries to the classical world. Given this diversity of opinions, German archaeologists have proposed the notion of *Randkulturen* to designate all those civilizations known to have been in contact with the classical world without fully merging with it: Scythians, Parthians, Germans, Phoenicians, Egyptians, and many others.

Chronology is not much better established. When the Archaic epoch was first identified, archaeologists knew nothing of the Minoan world and the palace civilizations of Greek antiquity, civilizations which later on would end being called preclassical. At the other end of the scale, the date commonly chosen to signal the conclusion of Greco-Roman history—the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.13015-6

fall of the occidental Roman empire in 476 AD—proves to be equally problematic: it takes no account of the persistence of the oriental Roman empire until the fall of Constantinopolis in 1453.

The History of Classical Archaeology

With its uncertain chronological and geographical boundaries (a problem admittedly shared with protohistory), classical archaeology stands somewhat apart from other, more global, strands of archaeology. It is both the oldest among these archaeologies, and the one most influenced by tradition: the ancient Greek word *archaiologia* retains within it all its meaning as a discourse on antiquity. It was, after all, in fifth century Greece that the historical genre first appeared, the reasoned discourse on the past to which the Greeks gave the name of *historia* (enquiry). And since Varron in the first century BC, the title of antiquary has been given to the man who seeks to interpret and classify ancient objects or monuments. In Greece as well as Rome, these antiquaries contributed to elucidate the past; they assembled series of objects and monuments, collected inscriptions, and then put them in order and sought to understand them.

In this respect, the collapse of the Occidental Roman Empire was not without consequence, for with it a whole social class of knowledge- producers and users came to disappear. Secular men of letters were gradually replaced by clerics, whose function was to educate the masses and the elite in the Christian faith. To be sure, there were among these clerics some antiquarians who undertook to collect and investigate the monuments of antiquity. But one has to wait until the end of the Middle Ages to find an antiquarian movement comparable to that of Greco-Roman times.

It was in Renaissance Italy that a new passion for antiquity emanated which was also a means for reinventing the contemporary world. Collections of Greek and Roman manuscripts arose passions, ancient coins were coveted, monuments begun to be excavated for the sculptures and architectural remains they may have contained. The past that was sought after and revived was that of Greece and Rome, if only because a reference to this world was seen as a means to do away with a present seen as barbarous, illiterate and indeed 'gothic.'

For Renaissance scholars, antiquity was quintessentially Greco-Roman: the literary works, sculptures and architecture of these periods were seen as unsurpassable productions, to be studied and emulated by the best contemporary artists. This classical focus dominated scholarly and artistic production until the end of the eighteenth century, and it explains that 'barbarian' antiquities received only marginal interest. The Renaissance has thus contributed to conflating the knowledge of the past with the investigation and understanding of the Greco-Roman heritage—the part of universal culture believed to be 'classic' by virtue of being the veritable pedestal of humanist scholarship. There were some scholars who manifested considerable interest for the oriental world, Egypt or even Mesopotamia, and others, particularly in Scandinavia, Britain and Germany, who paid attention to local antiquities, but the model for the organization of knowledge derived directly from the prestigious Greco-Roman tradition.

Renaissance scholars and their Enlightenment successors assembled together coins, inscriptions, sculptures, and sometimes even ceramics or other objects of daily life. These collections were displayed in 'cabinets of curiosity' and eventually came to adorn the first public museums, such as the Venetian collections and the Ashmolean Museum in Oxford (from 1683). However, since no careful observations were made regarding the place of discovery and the mode of manufacture of these collected works and monuments, it was only with the greatest difficulty that scholars were able to classify them in terms of their dates and provenance. In fact, it was only the antiquarians of the eighteenth century who were first able to lay the grounds of a critical analysis of archaeological monuments.

These advances occurred at different paces, and they were due both to discoveries in the field and to new attitudes towards finds and their study. In this respect, the fortuitous discovery of the buried cities of Pompeii and Herculaneum at the beginning of the eighteenth century did much to awaken the interest of the elite in the Greco-Roman world. What was being unearthed there by the excavating teams of the King of Naples were no longer usual ruins, but entire cities, covered by volcanic eruptions and thus miraculously preserved from the ravages of destruction. Closely guarded by the Neapolitan government, the exploration of Pompeii gave rise to an unprecedented craze for the painting, architecture and implements of daily life of the time. Given the context of their discoveries, these items could also for the first time be attributed a secure chronological position. Naples thus played the role of an antiquarian capital, and gradually came to compete with Rome in the esteem of travelers and connoisseurs.

Without interpretation, however, discovery is nothing. In the second part of the eighteenth century, two men revolutionized the understanding of antiquity. The first of these was Johannes Winckelmann (1717–68), a German scholar from a small Prussian town who achieved tremendous influence with his work. His *History of Art in Antiquity*, published in Leipzig in 1764, offered to amateurs of Greco-Roman art the first ever systematic and chronological treatise on the subject. Aided by a thorough familiarity with textual sources, Winckelmann depicted and commented on antique objects scattered throughout European collections. Drawing on his personal study of the most important Roman collections, he could propose to his readers a remarkable history of plastic forms in antiquity. The style of this work, the quality of its descriptions, and the philosophical spirit which animated it, all explain its unprecedented success: with it, the occident could at last discover the sources of Renaissance art in the classical world. Winckelmann, otherwise an enemy of the aristocracy and determined critic of the ancient regime, received his highest acclaim from the courts of kings and princes, among those who sought antiquity for the aesthetic pleasure it procured them.

One of the most notable aristocrats in the court of France, the Comte de Caylus (1692–1765), was instrumental in drawing the attention of his contemporaries to another aspect of the study of the past. For Caylus, what justified the quest for antiquity is not the aesthetic, but the technical achievements of the past. He therefore developed an approach to the study of past techniques in which can be recognized our current concerns with artifact morphology and archaeometry. Each in

his way, Winckelmann for the appreciation of art and Caylus for the understanding of techniques, laid down the bases for a history of the *oeuvres* of antiquity, a research programme developed and followed throughout the nineteenth century.

The Rules of Classical Archaeology

The exploration of antiquity thus gradually transformed itself into a new discipline of archaeology. Under this framework, nineteenth century scientists elaborated and imposed new rules for the extraction, analysis and publication of evidence from the past. Archaeology distanced itself from collections and from the social milieu of collecting, and advocated instead the necessity of observing finds in the field, and of recognizing them as coherent wholes open to rigorous analysis. While the antiquarian channeled his passion for the past to the collection of objects, the archaeologist aimed to valorise these objects and monuments in the context of their discovery. This approach found its most systematic expression in Germany with the research programme of E. Gerhard (1795–1867), who effectively fought for an autonomous archaeology, free from collectors, philologists and artists. Archaeologists must take the place of connoisseurs with their various intermediaries, and themselves seek for the evidence on the ground.

They must also distance themselves from philologists, and challenge the primacy of written over nonwritten sources. Finally, they must take leave of aesthetic considerations, and study ancient productions in all their material and technical dimensions. Building on advances in historical studies, this positivist program also drew on developments in geology and natural history to forge for itself its specific scientific instruments.

Three complementary pillars came then to form then backbone of archaeology. One, *stratigraphy*, consists of observing the conditions of deposition of objects and monuments in the ground. The second, *typology*, seeks to identity in the objects themselves some evidence regarding the time and place of their manufacture. The third, *technology*, deals with the modes of production, the raw materials, the procedures of fabrication. It was in fact only by the end of the nineteenth century, when these three strands were mastered and marshaled together, that archaeology became a fully-fledged discipline able to undertake the reliable and methodical investigation of the past. The body of doctrines and institutions which accompanied this development contributed to giving archaeology, and specifically to classical archaeology, its distinctive identity. In this respect E. Gerhard created a novel kind of institution which prefigures in many ways those of today: the *Instituto di corrispondenza archeologica*, established in 1829 in Rome through the activities of aristocrats and scholars from across Europe, took it as its aim to collect, excavate and publish as thoroughly as possible all the antiquities of the Mediterranean world.

By drawing archaeologists to the field, by elaborating a modern strategy of publication based on detailed sections and descriptions, the *Instituto* virtually launched the new discipline that was embodied in this dedicated research institution located in Rome, one of the capitals of the classical world.

Until the middle of the nineteenth century, the exploration of the Greco-Roman world had been a matter of individual enterprise with occasional royal support. From then on, archaeology would become what the discoverer of Greek Asia Minor T. Wiegand (1864–1936) has called a *Grosswissenschaft*, a state-sponsored science. The leading European powers established then various institutes or schools in Rome and Athens, and these encouraged archaeological expeditions throughout the main urban sites of the Mediterranean. The enormous success encountered by the private initiatives of the German businessman Heinrich Schliemann (1822–90) at Mycenae and Troy fueled a veritable scramble for new excavating territories among the countries of Europe and even America. This competition contributed notably to the growth of collections in the main European and American museums. The rise of such museums as the British Museum, the Louvre, the Berlin museums and even the Metropolitan Museum in New York, all catering for an ever-increasing public, corresponded with the ascendancy of a classical archaeology closely entwined with the economic developments of capitalism and colonialism. The conquest of the past was effectively an instrument of foreign policy in the hands of all main powers, beginning with the core area of the Greco-Roman world and reaching towards the Orient, Africa, and the globe as whole.

Archaeological schools, museums and, of course, universities were all part of this expansion, from which they have benefited. Whereas in the mid nineteenth century only Germany was endowed with a network of university Chairs in classical archaeology, by 1914 all European nations as well as the United States had established university curricula in classical archaeology. This three-pronged movement, involving the development of museum collections, the systematic excavation of sites, and the setting of an academic theoretical and educational framework, effectively gave to classical archaeology its modern appearance.

The Paths of Classical Archaeology

Set out during the second half of the nineteenth century, this disciplinary model witnessed during the first half of the twentieth century a considerable expansion and consolidation in both qualitative and quantitative terms. Alongside a marked increase in the number of excavations carried out, the main archaeological institutions followed the German model by systematically publishing catalogues of finds and collections according to specific descriptive protocols. This increased and refined considerably the existing knowledge on artistic and artisanal productions: sculptures, architecture, ceramics were all researched, and so were numismatics and glyptics. Thus classical archaeology forged itself a vast corpus of systematic reference, bearing equally on chronology, typology and technology.

Some criticisms and contradictions emerged, however, during the second half of the twentieth century. The implicit supremacy of Greco-Roman culture came under challenge; the comparative study of cultures raised questions over the Hellenocentrism characteristic of most Classical archaeologists, while advances in the study of mentalities promoted a critique of Eurocentrism.

The Greek and Roman worlds are now understood as melting-pots rather than *hochkulturen*. Under the influence of economic history, scholarly interest has shifted from a history of art in the narrow sense towards a wider history of productions. The better chronological grasp allowed by typological studies has served to advance studies on colonization, on long distance contacts and trade. Studies of the relations between centre and periphery, between Greeks, Roman and 'barbarians' have benefited from developments in the field of protohistory. It may indeed be said that the research program of classical archaeology has undergone a wide-reaching redefinition during the 1960s.

No longer considered as the elder of the sciences of antiquity, it is now one discipline among others, sharing resources and addressing issues similar to other strands of archaeology. In this context, such topics as the history of the landscape, or that of the movements of populations and the exchanges of goods and ideas, all open up new perspectives which contribute to extricate classical archaeology from its somewhat marginal position.

At the same time, advances in the iconography and the sociology of representations make it possible to cast a new light and reach a more satisfying understanding of otherwise well-known bodies of evidence. Thus, building on the strength of its centuries-long traditions as a science dedicated to Ancient art, Classical archaeology is developing now into to a human science in the full sense of the term.

Editor's Note

Archaeological work on Classical Period Europe continues apace. Indeed, every time a new construction is planned in Athens or Rome, classical archaeologists have a new excavation site to examine. Some recent works in the Classical world include: Alcock and Osborne (2012), Graves-Brown et al. (2013), Lulof (2014), Becker (2012).

Classical Conditioning Methods in Psychotherapy

William C Follette and Georgia Dalto, University of Nevada Reno, Reno, NV, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Classical conditioning describes associative learning where stimuli are sometimes paired to produce clinical problems including most anxiety disorders. Extinguishing problematic responses that arise through classical conditioning is the focus of many psychotherapy procedures. This article describes the basic principles of classical conditioning, how understanding these principles helped clarify our understanding of the etiology of clinical problems, and how exposure-based treatments were developed to reduce or eliminate these problems. Recent cognitive explanations regarding the change process in humans are described. Finally, some attempts to add pharmacological adjuncts to improve the efficacy of exposure are reviewed.

One of the most common reasons people seek psychotherapy is because of anxiety or fear about some situation or object. There are many accounts for how these emotional states develop, but when people present for therapy it is often because their avoidance of these fearful situations interferes with some aspect of their desired role functioning. One of the most commonly used technical procedures in psychotherapy is exposure, and it is particularly effective in the treatment of these types of clinical presentations. The effectiveness of exposure hinges primarily on an understanding of classical conditioning, also called Pavlovian or respondent conditioning.

Classical conditioning is commonly defined as a process whereby a previously neutral stimulus comes to exert control over a response through pairing of the neutral stimulus with a stimulus that naturally (i.e., with no prior training) elicits the response. Since its accidental discovery by the Russian physiologist Ivan Pavlov in the late-nineteenth century, classical conditioning has been applied to many normal as well as clinically significant behaviors such as those characterizing anxiety disorders and addiction. Using principles derived from classical conditioning theory and contemporary extensions of the theory, behavior therapies have been developed to reduce the fear and anxiety responses that interfere with normal functioning.

The Procedures and Processes of Classical Conditioning

Classical conditioning is the most straightforward example of associative learning where stimulus–stimulus associations develop. According to the above description, the stimulus that naturally elicits the response is known as the unconditional stimulus (US), the naturally occurring response is known as the unconditional response (UR), the previously neutral stimulus is known (following conditioning) as the conditional stimulus (CS), and the response that comes under the control of the CS is known as the conditional response (CR). The process was first outlined by Pavlov during his study of the salivary response in dogs. Food in the mouth naturally produces a salivary response to aid digestion, but Pavlov noticed that his subjects began to salivate to the sound of a bell that accompanied the opening of the laboratory door during feeding time. In a series of now classic experiments, Pavlov demonstrated that the bell became a CS for the food (US) and that the CR of salivation was very similar to the natural salivary response (UR) elicited by the food.

For the better part of a century, contiguity between CS and US was commonly cited as an essential determinant of the successful conditioning of a response. Optimal conditions were said to be those in which the CS simply occurred immediately before onset of the US. However, more recently, the focus has shifted from contiguity between the CS and US to the amount of information supplied by the CS about the occurrence of the US (Rescorla and Wagner, 1972). For example, if a US occurs as frequently (or more frequently) in the absence of the CS as in its presence, very little conditioning will occur. The CS in this case is simply a poor predictor of the onset of the US. To exemplify the basic procedure by which a conditional response to a previously neutral stimulus is established, consider the following example. A small child with no fear of dogs is playing near a dog's food bowl. As the dog approaches, the unsuspecting child reaches out playfully to pet it. The dog (CS), presumably guarding its food, nips the child (US), causing minor tissue damage and producing a fear response in the child (UR; e.g., crying, retreating, etc.). If the child emits a fear response (CR) when next confronted with the sight of a dog (CS) and in the absence of another nip, conditioning is shown to have occurred. Earlier descriptions of classical conditioning also stated that the CR was generally topographically similar to the UR. That is, the CR looked the same. It is now recognized that the CR may look different from the UR depending on the species of the organism. In humans, the nature of the CR may vary substantially from the UR.

Generalization and Discrimination

Two other processes are relevant to a discussion of classical conditioning in clinical psychology: generalization and discrimination. In stimulus generalization, the CR occurs to stimuli that are similar in some way to the CS (but to which the response has never been conditioned). If the child was bitten by a Golden Retriever, but then comes to emit the fear response in the presence of German Shepherds and Chihuahuas, stimulus generalization is said to have occurred. In nonverbal organisms, generalization occurs on the dimension of some shared property of the stimulus. For example, if a dog were

 http://dx.doi.org/10.1016/B978-0-08-097086-8.21052-0

classically conditioned to a tone of a certain frequency, then similar sounding tones could also elicit a CR. In humans, language allows other generalization to occur along dimensions that may share no formal properties with the original CS but have acquired a relationship with the CS that can produce a CR. For example, only humans can show conditioning to the sight of a dog (CS) and also to the word 'dog' or the name 'Rover' or a leash, without prior conditioning once the animal has become a CS. In stimulus discrimination, the CR does not occur to stimuli that differ sufficiently from the original CS. In this case, the child would only fear Golden Retrievers, and would not emit that response to other breeds.

Exposure to the US or the CS: Habituation and Extinction

The process by which a fear response can be learned was described above. This same response can also be inhibited. One or both of the following processes can be used clinically to reduce fear responding. The first process is called habituation and it occurs through the repeated presentation of the US without the CS. The CS comes to have no predictive value for the occurrence of the US such that later presentations of the CS do not elicit a CR. The other process that can lead to inhibition of the CR is called extinction. Extinction is when the CS is presented without an accompanying US. A tone may be presented to a dog but food no longer follows. Eventually, the predictive value of the CS is diminished such that the CS no longer produces a CR.

Classical Conditioning and Avoidance in the Development of Psychopathology

The example of the child and the dog demonstrates the potential for classical conditioning to play a part in the etiology of a severe and persisting fear of dogs, or simple phobia, and it identifies a pathway through which many other fear or anxiety related disorders are thought to develop. Watson and Rayner (1920), in their classic Little Albert experiment, effectively conditioned fear in an infant. After allowing the child to play with a white laboratory rat (to which he showed no previous fear), the researchers followed presentation of the rat (CS) with a loud bang on an iron bar behind Little Albert's head. The loud noise (US) elicited a startle response from the child (UR), accompanied by crying. After a number of trials with this pairing, Little Albert began to emit a fear response (CR) to presentation of the rat alone, a response that also generalized to other white, furry objects. The clinical significance of this response (i.e., its persistence and the degree of functional impairment it produced) is not known, as Little Albert did not participate in follow-up studies and is thought to have died at age six (Beck et al., 2009). However, one of Watson's later graduate students, Mary Cover Jones, did demonstrate that phobic responses could be reduced by gradually exposing a child to the feared object (Jones, 1924).

People can also learn fear responses without directly experiencing the CS–US pairing, but can instead learn through observation. When someone observes a dog bite a person resulting in injury and distress, the observer may acquire a conditioned response. This is called vicarious learning. One can acquire even more subtle associations such as when a child is holding a parent's hand and notices a hand squeeze and protective movement when the parent sees a strange, large dog. Though many adults with specific phobias can recall a CS–US pairing, a large number of such people have no such recall. While it is possible that some of these reports are simply failures of memory, this also suggests that vicarious learning can account for some proportion of episodes of conditioning.

Not all stimulus–stimulus relationships are equally easily established (Garcia and Koelling, 1966). Certain modalities of associations are learned more readily than others. For example, pain is more readily associated with visual or auditory stimuli than gustatory stimuli (Rachman, 1991). Conversely, internal stimuli are more readily conditioned with gustatory stimuli. Thus, it is common for taste aversions to be acquired after an episode of nausea or vomiting (Bernstein, 1999).

Individual Differences

Not everyone who experiences a potentially traumatic event will go on to demonstrate the pathological avoidance or exaggerated startle responses characteristic of post-traumatic stress disorder (PTSD), nor indeed does everyone exposed to a fear-inducing US develop conditioned fear or a phobic response to the accompanying CS. Again, classical conditioning principles may help shed some light on this individual difference. The concept of 'conditioned inhibition' suggests that when the CS is a compound stimulus (e.g., all the myriad stimuli that make up the context in which an event occurs), the stimuli that signal the absence of the US will inhibit conditioned responding. Consider the example of a child who is with her mother when a bomb goes off on a bus. Because the presence of the child's mother has, through previous conditioning, come to signal safety (or the absence of danger), the child may not develop a conditioned fear response to other stimuli present at the time of the explosion (e.g., loud noises, buses, etc.). In this case, the child's mother has served as a conditioned inhibitor and effectively protected the child from developing a pathological fear response to the neutral stimuli.

The principles of stimulus generalization and discrimination can also help explain individual differences in psychopathology. When fears become pervasive (such as when a rape victim comes to fear all men), it is likely due to extensive stimulus generalization. Many things have come to participate in a stimulus class with the original CS because they are similar on some relevant dimension (e.g., they are all male). Alternatively, very circumscribed fears are the result of appropriate stimulus discrimination (as when an individual avoids the intersection at which he had a serious automobile accident but is still able to drive through all other parts of the city).

Individual differences in reactivity to potentially fear-inducing events also depend on the unique learning histories of the individual. One way histories differ is in terms of prior experience with stimuli. The Kamin 'blocking' effect states that a stimulus that is part of a compound stimulus will fail to produce conditioning if other stimuli in the compound have already been conditioned (Kamin, 1969). A boy who has come to emit a fear reaction at the sight of soldiers in uniform because they were present when he arrived home to find that his mother had been killed in an airstrike, may not come to fear news reporters who are present (in addition to soldiers) when

the rest of his family is killed in a similar attack 2 weeks later. The blocking effect is thought to occur because the second stimulus does not provide any new information about the US beyond that supplied by the original CS.

Avoidance

If classically conditioned fear responses reduce on their own when either the CS is presented without the US, or the US is presented without the CS, then why don't fear responses naturally ameliorate? In fact, some do (Staley and O'Donnell, 1984). Epidemiologic studies do show that children endorse a higher number of feared objects than do adults, though some fears develop later (Merckelbach et al., 1996). What accounts for the diminution of the feared objects as people get older? The answer is likely natural exposure that occurs during the course of childhood. If a child is showing a fear of a dog known to be friendly, parents or the dog owner may well slowly present the dog for petting by the child or may model petting after which the child does the same. This kind of natural exposure produces extinction and is likely why the prevalence of specific phobias decreases over time.

What accounts for when fear responses persist? A version of the answer was offered by O.H. Mowrer (1956) called two-factor learning theory. In its simplest form, the theory argues that fear responses are classically conditioned in roughly the way described above. It is the second factor that interferes with the natural reduction in the fear response: avoidance. Avoidance occurs when someone begins to encounter either the feared stimulus, the US, or stimuli that have become conditioned to elicit the feared response. As the fear rises, the person avoids contact with either the CS or US. This avoidance behavior is negatively reinforced, i.e., made more likely to occur (see operant learning) by the reduction or removal of fear or anxiety. The clinical implication of this avoidance is that the person does not experience either habituation or extinction, because the aversive stimulus in never repeatedly contacted so that habituation or extinction would occur. Going back to the simple example of the person fearful of dogs, when such a person sees the dog from some distance away, a mild aversive response may be noted. As the dog gets closer, the anxiety rises. If the person turns around and exits the situation, the anxiety or fear quickly reduces. This reduction in the aversive emotion negatively reinforces avoidance. In the short run, the aversive state is removed thereby strengthening the avoidance. Had the person continued to approach to dog in spite of the growing anxiety, the person would have come right up to the feared object, the dog, and not have experienced a bite. If the approach behavior continued in other episodes, the fearful response to dogs would have habituated. Though Mowrer's original formulation has been extended to include cognitive components to address how widespread avoidance of various stimuli can become, its treatment implications are still generally relevant, as will be discussed below.

Exemplars

People with PTSD show exaggerated startle responses and report intense fear reactions to many stimuli that were present at the time of the original traumatic incident (e.g., the sound of a helicopter for a combat veteran, the presence of crowds for a survivor of a mass shooting, darkness or the smell of alcohol for someone who was raped in an alleyway outside a bar late at night). In all of these examples, previously neutral stimuli have come to elicit a fear response very similar to that elicited at the time of the trauma. The stimuli that elicit the fearful response are external to the person.

Panic disorder (sometimes described as fear of fear) is characterized by intense fear responses to interoceptive (as well as external) cues such as a pounding heart, dizziness, shortness of breath, sweaty palms, or symptoms that may have preceded a full-blown panic attack in the past. In this case, the initial (and extremely unpleasant) panic attack can be thought of as the US, fear of dying may be the UR, the early symptoms or environmental conditions as the CS, and the fear response as the CR. Since panic attacks may be perceived as occurring randomly, any aspect of the environment may become a CS as might any unpleasant physical sensation.

In some cases, panic attacks may lead to the development of agoraphobia, literally a fear of public (open) spaces, but clinically a fear of being in a public place where one feels trapped or faces embarrassment should a panic attack ensue. The person tries to identify situational cues that will allow him or her to avoid a panic attack. Since the cues are difficult to detect, the person generalizes those situations broadly and avoids more and more activities that take place away from the relative safety of one's home.

Anxiety disorders in general rely on treatment components that derive from classical conditioning models. An individual with social phobia may learn to avoid all manner of social interactions or performance situations, because characteristics of these contexts have been associated with humiliating experiences in the past.

Certainly, addictive behaviors have many classically conditioned elements to them. The sight of needles, drug paraphernalia, the olfactory or visual cues, or the appearance of another drug user may elicit cravings in alcohol, opioid, or stimulant abusers.

Using Classical Conditioning in Psychotherapy

In addition to helping explain the etiology of many forms of psychopathology, an understanding of classical conditioning principles has given rise to several forms of behavioral psychotherapy. Beginning with Mary Cover Jones, 'counter-conditioning' involved the pairing of a feared stimulus with an appetitive (desirable) stimulus such that the response to the former was replaced with the response to the latter.

Sensitization

One line of therapy based on classical conditioning was developed to reduce behaviors desired by patients but that were recognized to be unhealthy or otherwise undesirable. One of the more common examples can be found in the history of the treatment of alcohol dependence where conditioned taste aversions are used to treat this difficult problem. As with many clinical problems, treatment can be understood from either a classical or operant conditioning perspective (or both). One

treatment strategy has been to classically condition the taste or smell of alcohol with nausea by using conditioned taste aversion procedures (Revusky, 2009; Lemere, 1987; Reily and Schachtman, 2009). As mentioned earlier, gustatory–nausea relations are more easily learned than some other sensory modalities. Two procedures are most common. In one, after the risk of alcohol withdrawal has been managed, the patient is given a taste of a preferred alcohol followed by an emetic drug (Lemere, 1987). Emetics induce nausea or vomiting. The notion is that alcohol when paired with the emetic will produce a response of nausea to the alcohol in the absence of the emetic. A variation on this approach is the use of disulfiram (Antabuse™) in alcohol treatment programs (cf Krampe et al., 2011; Jørgensen et al., 2011; Alharbi and el-Guebaly, 2013). Disulfiram is another commonly used drug that provides a similar learning history. Disulfiram interferes with the normal metabolism of alcohol resulting in a buildup of acetaldehyde. This can lead to nausea, vomiting, dizziness, and other unpleasant side effects when one drinks alcohol, thus creating a conditioned taste aversion.

Alcohol treatment programs have also tried to use aversive electrical stimulation paired with alcohol taste to create a conditioned aversion to alcohol as well. There is less evidence that the shock–alcohol pairing is clinically as effective when compared to the emetic–alcohol pairing, though the limited evidence is not consistent (Smith et al., 1997; Cannon et al., 1981; Lamon et al., 1977). There have been ethical objections to conditioned aversive therapies (Nathan, 1985; Wilson, 1987), but some patients find them a better alternative than other treatment programs or compared to continued addiction.

Conditioned aversion therapies have been applied to a variety of behaviors, the consequences of which can have deleterious effects for those who exhibit them, or for society. Aversion therapy has been adapted to smoking, cocaine use, sexual deviations including child molestation, and paraphilias, to name some examples (Rachman and Teasdale, 1969).

Covert Sensitization

Though not purely involving classical conditioning procedures, covert sensitization, also called covert conditioning, has been used to treat maladaptive approach behaviors including but not limited to problematic compulsions, sexual behaviors, alcoholism, obesity, nail biting, and smoking (Cautela and Kearney, 1986; Cautela, 1971). This procedure was developed as an alternative to the application of aversive stimuli such as an electric shock or an emetic (cf Krampe et al., 2011; Jørgensen et al., 2011; Alharbi and el-Guebaly, 2013). Covert sensitization makes use of aversive imagery that may be easier to produce outside of the laboratory or treatment environment. In brief, the subject is taught to imagine himself as about to engage in some desired but problematic behavior such as taking a drink. Vivid cues are provided to enhance the image. As the person is about to take the drink, he is instructed to imagine an uncomfortable feeling taking over that results in a further image of feeling profound nausea followed by vomiting. The vomiting is imagined to result in vomiting on oneself, the table, and perhaps others. The person is instructed to imagine odors, being embarrassed, and perhaps other aversive consequences. This process is repeated. In some versions, the person may be taught to imagine being about to take a drink, feeling the beginning of the nausea, and stopping, which is followed by a feeling of relief and pride that one resisted the drink.

It is not easy to measure how well the covert stimuli are produced or to assess how well or how willing one is able to produce the aversive covert stimuli. Nevertheless, this procedure can be useful when one behaves under the control of a reinforcer that is inappropriate or leads to undesirable consequences.

Systematic Desensitization

Joseph Wolpe was among the first to use the term 'systematic desensitization' for his approach to reducing fear responses to anxiety-producing stimuli (Wolpe, 1961). In this treatment, a relaxation response is trained in advance of exposure to the feared stimulus. When the feared stimulus is introduced, the client is instructed to engage in the relaxation response, which is believed to be physiologically incompatible with the fear response (Wolpe originally use the term 'reciprocal inhibition'; see Wolpe, 1958 for an early explanation of the intervention). Typically, there are three steps to this treatment. One is to identify a hierarchy of situations that are increasingly fear-provoking for the patient. In the case of acrophobia (a fear of heights), the patient and therapist list a series of such scenes from looking at a short step ladder to standing in front of this ladder to stepping on the first step. Additional scenes are constructed culminating with the most challenging scene that might be standing on the ledge of a tall building and looking down at the street below. In a commonly practiced version of this treatment, the scenes are sorted from the lowest arousing scene to the highest. Some number of sessions are used to teach the subject relaxation skills. Once those skills are learned, the therapist has the person imagine approaching the first element of the hierarchy until they notice some uneasiness, at which point they are told to use their relaxation skills until they become comfortable. This is repeated until that element of the hierarchy no longer produces anxiety or fear, and then the next scene is presented. This process is repeated until the client completes the hierarchy. Some have proposed that the process involves extinction, while others suggest habituation takes place (Watts, 1979). In either event, the previously avoided stimuli are contacted and the anxiety response is sufficiently reduced to allow normal functioning.

When treatment is designed as described above, it is often experienced as more palatable for both the client and therapist. As research has shown, it is not actually necessary for the hierarchy of scenes to be presented in a particular order; nor is it essential that the client have mastered a relaxation response; and some data indicate that *in vivo* exposure to elements in the hierarchy are perhaps more effective than imaginal techniques (see Marks, 1978 for a review). Thomas Stampfl introduced the technique of 'flooding,' in which the client is exposed to large doses of the feared stimulus and prevented from escaping until the fear response subsides (Stampfl and Levis, 1967). Contemporary treatments such as prolonged exposure for trauma and exposure and response prevention for obsessive-compulsive disorder (OCD) were built on this tradition of harnessing the power of classical conditioning to replace maladaptive responses with more adaptive ones. What all these

techniques have in common is that they involve exposing the client to the feared stimulus instead of allowing him or her to continue to avoid it.

Over the last 25 years, several difficult-to-treat problems have been successfully addressed by creative exposure procedures. Panic disorders have been treated by making use of interoceptive exposure where some of the symptoms of panic are produced but without the panic attack itself (Barlow et al., 1989; Barlow and Craske, 1989). Many who experience panic attacks become hypersensitive to normal physiological responses such that when they occur, fear of a panic attack ensues. In interoceptive exposure procedures, a variety of exercises are used to bring about some of those internal sensations so that the fear of a panic attack does not occur when some cues occur. For example, patients are taught to hyperventilate to experience some lightheadedness. Similarly, a patient may sit on a chair that spins around sufficiently to induce mild dizziness. A variety of exercises are utilized to expose patients to bodily cues that do not become panic attacks.

OCD is another clinical problem that has been usefully treated by exposure and response prevention (Franklin and Foa, 2011). In OCD, patients are exposed to that about which they obsess and are prevented from exhibiting the compulsive behavior that they use to reduce the obsessions. For instance, someone who obsessed about germs might be exposed to a dirty article of clothing for long periods of time and not allowed to wash his hands.

Debate exists with regard to the mechanisms by which exposure reduces fear and anxiety (McSweeney and Swindell, 2002). Traditionally, this process has been described as extinction, whereby the CR fails to occur following repeated presentation of the CS without the US. The CR is said to extinguish as a result of this procedure. The idea is that the link between CS and US is severed, so that the CS no longer predicts the US. According to Rescorla–Wagner model, this procedure would diminish the information about the US provided by the CS. However, McSweeney and Swindell (2002) examined the substantial body of literature available at the time and concluded that there is considerable evidence to suggest that the process known as extinction actually relies on the even more basic principle of habituation. Habituation is defined as "a decrease in responsiveness to a stimulus when that stimulus is presented repeatedly or for a prolonged time" (p. 364–365). When applied to the senses, habituation is known as 'sensory adaptation' and it is a process so pervasive that we often take it for granted (consider the experience of walking into a room with a strong offensive odor and suddenly realizing half an hour later that you can no longer smell it). The case presented by McSweeney and Swindell suggests that repeated or prolonged exposure to the CS will cause a decrease in the probability or likelihood of the CR through this process of habituation. It remains an empirical question whether habituation occurs to the CS through repeated or prolonged exposure even when the CS continues to be followed by the US.

Treatments based on classical conditioning principles also consider such effects as stimulus generalization and discrimination, blocking, and conditioned inhibition. The tendency of fears to generalize to additional stimuli can make treatment challenging, as many more stimuli than those involved in the original fear-inducing event may need to be targeted in treatment. On the other hand, one expects that treatment produces new learning (i.e., to not fear the stimuli used in exposure) that will generalize to additional feared stimuli.

However, the situation is complicated, as habituation and extinction appear to generalize less readily than the original conditioning (McSweeney and Swindell, 2002). Stimulus discrimination can be encouraged by training the individual to distinguish between the original feared stimulus and similar (but different) stimuli. This process may help prevent the generalization of the fear response following the original conditioning event. Blocking could potentially prevent new learning from occurring such that it may be more effective to conduct exposures to one feared stimulus at a time; pairing a reconditioned stimulus with one that is still feared may render the still feared stimulus redundant (i.e., it does not provide any new information about the situation).

The impact of conditioned inhibition on psychotherapeutic techniques informed by classical conditioning may be more complicated. While the presence of a stimulus that has come to signal safety may protect the individual from fear conditioning to begin with, such 'safety signals' may also impede the process of extinction/habituation during exposure. It is thought that safety signals (such as empty medication bottles or being accompanied by a significant other during exposure exercises) prevent the individual from fully contacting the feared stimulus so that when exposed to the stimulus in the absence of the safety signals, any apparent positive effects of the exposure disappear.

Cognitive Considerations

Certainly, exposure-based therapies are among the most robust intervention for the treatment of anxiety disorders. Exposure relies on some aspects of classical conditioning principles augmented by an operant understanding of the role of avoidance in the maintenance of anxious or fearful response. Two observations have stimulated theorizing about a cognitive explanation for how exposure works. First, not everyone who undergoes an exposure-based treatment shows improvement (Choy et al., 2007). This implies that our understanding of the dimensions of the CS or CR is not fully adequate. Second, the treatment of two difficult clinical problems, PTSD and OCD, has engendered theorizing about what happens in humans who can verbalize their experiences (Foa and Kozak, 1986). In PTSD, a wide variety of stimuli, not easily categorized, can produce fearful responding. In OCD, obsessions are cognitions and patients provide elaborate explanations for the source of the obsessions and the functions of the compulsions.

One of the more elaborated information processing/cognitive models was called emotional processing theory (EPT) (Foa and Kozak, 1991; Foa et al., 2006). EPT suggests that effective treatments for fear and anxiety, including exposure, produce their effects by introducing accurate information to alter existing, or create new, fear structures. A fear structure contains memories about sensory information about the feared situation, the avoidance behaviors and one's reactivity to the situations, and information about the interpretations relating the stimuli and responses. The basis of the prolonged exposure, an effective but not the only treatment for PTSD, is that fear

structures associated with the traumatic memory entail incorrect associations between stimuli and responses during the trauma and its subsequent meaning. The set of stimuli recognized and responded to as dangerous is too broad, meaning that fear is experienced to a wider set of stimulus conditions. The person also understands their responses as incompetent in indicating they cannot cope. This results in an inability to take in new experiences that would alter their emotional processing. Prolonged exposure putatively works by promoting alterations of the fear structures through systematic confrontation of trauma related stimuli (using imaginal exposure) with discussion of the experience in order to help disconfirm the problematic beliefs. The result is the modification of the problematic fear structure or the creation of another more adaptive one.

Not everyone agrees with the need for or the accuracy of this conceptualization and some suggest genetic and individual difference variables warrant attention in addition to remaining aware of advances in associative learning (e.g., Mineka and Thomas, 1999; Mineka and Oehlberg, 2008). In either case, as the verbal constructions of the fear-evoking stimuli get more elaborated, so too does theorizing. This perhaps follows from the natural language patients use to discuss fearful situations and responses to them, as well as the Rescorla and Wagner use of the concept of information contained in the relationship between the CS and US, again a use of language that promotes a more mentalistic interpretation of emotional responding and its treatment.

Future Directions

New technologies such as virtual reality are being applied to simulate *in vivo* exposure to otherwise difficult-to-create stimulus conditions (see Virtual Reality in Psychotherapy). For example, virtual reality goggles and sounds have been used to present combat situations for those who show clinically significant fear and anxiety responses following wartime experiences. This same technology has been used to present cues for high-risk situations such as gambling opportunities and smoking situations where the cues themselves may be conditional stimuli for these inappropriate behaviors or discriminative stimuli from an operant learning perspective. Virtual reality scenarios can be programmed for the treatment of generalized anxiety disorder where many different kinds of stimuli can elicit anxiety. Increasingly, technology is expanding into the therapy environment.

It is clear from the principles of change purported to underlie many of the empirically supported treatments for anxiety that classical conditioning principles have contributed significantly to the arsenal of interventions currently available to psychotherapists. However, the field would likely benefit from the further explication of the precise mechanisms that account for the improvements seen with these therapeutic techniques. Among these are the issue of whether extinction is a distinct process from habituation, how the unique learning history of the client can assist or impede treatment, and the extent to which classical and operant conditioning interact both in the etiology and the resolution of psychopathology.

Interesting pharmacologic interventions that possibly affect mechanisms of memory (re)consolidation are currently being researched. There is some evidence that propranolol, a β-adrenergic blocker, may reduce PTSD symptoms, but the ethics of such interventions have been debated (Donovan, 2010). There is evidence that the extinction of fear is mediated in the basolateral amygdala by the activation of N-methyl-D-aspartate (NMDA) receptors. The drug D-cycloserine can indirectly enhance that activity and has been shown to enhance fear extinction in exposure procedures in both animals and humans, though that effect may only be present if fear is lowered during a session (Smits et al., 2013). Given the ubiquity of anxiety disorders and the public health costs in terms of treatment, resource utilization, and lost productivity, it is likely that procedures to make extinctions procedures more available and cost-effective will continue to evolve.

Abstract

Latin and Greek social and political thoughts, particularly as preserved and discussed in the international language of Latin, influenced ideas of natural law, liberty, public virtue, and republic and empire as models of government, particularly in medieval and early modern Europe, colonial America, and imperial Britain. Plato was invoked for and against twentieth-century political absolutisms and the emerging sciences of anthropology and psychoanalysis drew on classical sources for ancient legend and evidences of primitive religion and ritual as source material and conceptual models. Plato, Aristotle, and, earlier, pre-Socratic, Greek philosophy have remained reference points for phenomenologists and other modern thinkers.

The philosophers, orators, and historians of ancient Greece and Rome, particularly Plato, Aristotle, the Stoics, Cicero, Livy and Tacitus, together with Virgil as the poet of empire and Homer as witness to the dawn of European civilization, are the main sources of the ideas and attitudes of classical antiquity which had a significant afterlife in the social and behavioral sciences.

Ancient Rome, the first and greatest beneficiary of Greek culture and thought, bequeathed its laws, its language and much of its ordered civilization to the west. The Greek city-states, particularly Athens and Sparta, the Roman Republic and the empires of Alexander the Great and of the Caesars, with all their strengths and weaknesses, provided later states and statesmen as well as political thinkers with contestable models of political organization. Particularly in the era of the French Revolution, invocations and discussions of political freedoms lost and won in Greek and Roman history reflected and expressed modern fears and preoccupations. The very vocabulary of political discourse continued to be strongly classical: 'politics', 'democracy', 'economics', and their equivalents in most European languages come from the Greek; 'republic', 'empire', and 'senate' are from Latin, and Latin continued to be the international language of intellectual exchange, including social and political theory, down to the end of the eighteenth century.

The classical architecture of town halls and other civic or national buildings across Europe and North America indicates continuing respect for classical traditions of public life. The more or less exemplary lives of classical heroes, and occasionally heroines, many of them recorded by Livy or collected by Plutarch, were frequently retold and revisited in the schoolroom. Parallels with celebrated classical achievements in word and deed were invoked in city squares and other public places by bronze or sculpted statesmen in togas, or soldiers on horseback on the model of Roman equestrian statues. The massive nineteenth-century Statue of Liberty in New York Harbor represents the classical goddess Libertas whose temple had stood on the Aventine Hill in Rome. Triumphal arches such as the Brandenburg Gate in Berlin (1788–91), the Arc de Triomphe in Paris (1806–36), and the Marble Arch in London (1825), all based on surviving classical models in Athens and Rome, celebrated modern victories and victors. The *fasces*, or bundles of rods bound with red thongs carried in procession to symbolize the power of ancient Roman magistrates, lent their symbolism and their name to Italian Fascism. The myths and rituals actually or arguably represented or implied in classical sources, particularly in the poets and in Greek tragedy, stimulated and helped to formulate new kinds of understanding in the course of the nineteenth century, particularly in the emerging sciences of anthropology and psychoanalysis.

Plato's influence as a moral and political philosopher, particularly in the *Republic*, was widely acknowledged in antiquity and supplied a basis for subsequent discussions such as Aristotle's *Nicomachean Ethics* and *Politics*. Plato and Aristotle between them provided later ages with nuanced conceptual vocabulary, models of dialectical, skeptical and logical inquiry, analytical tools and specific arguments. But the influence was sometimes indirect. After the fall of Rome in the fifth century, there was comparatively little direct access to Greek sources in Western Europe until the Renaissance. Aristotle, read in Latin versions, suffered the further misfortune of being too closely associated with medieval prescientific approaches to the natural world, in time vigorously repudiated by Francis Bacon (1561–1626) and others. But Plato and Aristotle lived on in the teachings and speculations of the Latin Church fathers such as Augustine. Works of Aristotle and other Greek writers which might otherwise have been lost were preserved in Arabic versions, eventually translated into Latin. The Greek-educated Cicero, reflective statesman, orator, lawyer, and exemplary Latin stylist, continued to be widely read and respected, and this helped to preserve awareness of Greek thought. His works on ethics (particularly *De officiis*), politics (*De republica*), and law (*De legibus*) preserved arguments, examples, and ideas which drew extensively on the Greek tradition.

Cicero and Law

Plato had developed a discussion of justice in the second book of the *Republic*, and Aristotle had considered it in the fifth book of the *Nicomachean Ethics* as an aspect of moral virtue. But Cicero was probably the most important direct source of ideas and aphorisms about justice and law invoked by later social thinkers, a major influence on the development of natural law theory in Thomas Aquinas's *Summa Theologiae* (1274) and the Dutch jurist Hugo Grotius' *De Iure Belli et Pacis* (1625). Cicero features much more prominently than Aristotle in the Swiss

philosopher and diplomat Emer de Vattel's *Droit de gens* (1758). Cicero's contention that *salus populi suprema lex*, the safety of the people should be the supreme law (*De legibus* 3.3.8) was invoked in John Locke's *Second Treatise on Government* (1690) as a 'just and fundamental' principle (13.158) and quoted as axiomatic in the radical republican Algernon Sidney's *Discourses concerning Government* (1698) (2.7) and elsewhere. Particularly admired in Britain and America, the phrase was adopted as the motto of the London Borough of Lewisham and of the State of Missouri. Drawing on the Stoic theory of a world soul or God as the ultimate sanction for law and morality, Cicero posited a natural law, grounded in the reason which was shared by God and man (*De legibus* 1.6,7), unwritten but innate in humanity (*non scripta, sed nata lex*), to which men might appeal, given the imperfections of formal law (*Pro Milone* 4). His principle that law, derived from the will of the gods, commanded what is honorable and forbade the contrary (*Philippics* 11.12.28), was quoted (in simplified form) by the thirteenth-century English jurist Henry de Bracton in his *De Legibus et Consuetudinibus Angliae*. It was repeated by Algernon Sidney (*Discourses* 3.10, 3.21) and invoked in William Blackstone's discussion 'Of the Absolute Rights of Individuals' at the beginning of his magisterial *Commentaries on the Laws of England* (1765–69) studied in rights-conscious America as well as in Britain (Sellers, 1998). It was a kind of backhanded compliment to Cicero's enduring reputation and influence as a theorist of political freedom under the law and opponent of arbitrary government that he was unfairly attacked by Thomas Hobbes (*De Cive*, 1642, 12.3) as one of the patrons of Greek and Roman 'anarchy', together with Aristotle and others.

Cicero, with Aristotle, contributed significantly to the developing political thought of colonial America (Botein, 1978). The patriotic Patrick Henry's famous rallying-cry 'give me liberty or give me death', spoken at the second Virginia Convention in 1775, was modeled on Cicero's alternatives of *libertas* and *mors* in *Philippics* 8.10.29. Thomas Jefferson specifically mentioned Cicero, along with Aristotle, as contributing to a tradition of 'public right' informing his draft of the American Declaration of Independence, and in his *Defense of the Constitutions of Government of the United States of America* (1787–88) John Adams invoked the authority of Cicero as a statesman as well as a philosopher who understood that the state needed to set bounds to ordinary factional behavior and find a balance of interests.

Livy, Tacitus, and Republican Virtue

In colonial America, as in Florence and Geneva in earlier days, political theorizing often fed on more or less stylized accounts of political life and public virtue in the ancient world. Livy's *History of Rome* provided Dante with examples of political virtue in *Monarchia* (*c.*1318), his Latin treatise on political philosophy. The Florentine Niccolo Machiavelli's *Discorsi* (1517), based on the first 10 books of Livy, which deal with the Roman republic, is in effect a treatise on the problems of establishing a durable republican polity in Florence. The radical Genevan Pastor Antoine-Jacques Roustan, who admired the work of Rousseau, resurrected the praise of classical republicanism as Livy described it in his *Dialogues entre Annibal et Tite-Live* (Geneva, 1789). Lucius Junius Brutus, prototype of republican virtue in that he delivered Rome from the monarchical tyranny of the Tarquins and helped to inaugurate the Roman Republic, perhaps the supreme Roman exemplar of uncompromising public duty (Livy 2.5) was celebrated in Voltaire's tragedy *Brutus* (1730) and became something of a cult figure in the early days of the French Revolution.

Tacitus began his *Annals* by saluting this Brutus as the father of Roman liberty. Laconic, epigrammatic, shrewdly pessimistic about Roman political culture as he had experienced it, Tacitus was much admired both for style and substance by the essayists Bacon and Montaigne in the sixteenth century. Tacitus lived under the Roman Empire and accepted that it was a permanent institution, but he was savagely critical of the more vicious emperors and claimed at the beginning of his *History* that Empire brought about the vanishing of great minds. His combination of moral indignation, political pragmatism, and rhetorical skill in conveying different points of view allowed him to be used on different sides in political argument. Leonardo Bruni, in his *Panegyric to the City of Florence* (1404), found ample support in Tacitus for his commitment to the republican form of government. He objected to Dante's admiration for Julius Caesar as founder of the Roman Empire and his consequent assigning of Caesar's assassins (Marcus) Brutus and Cassius to the deepest part of Hell in the *Inferno*. Though the foundation of Florence was usually associated with Caesar, Bruni went out of his way to attribute it to the republican general Sulla, at a time when the Roman people still flourished in an allegedly free and unconquered state. Other scholars, notably the Dutch humanist Justus Lipsius, read Tacitus rather differently. In his *Politicorum sive civilis doctrinae libri sex* (1589), much reprinted in Latin and translated into English in 1595, he insisted that Tacitus showed that the interests of peace were best preserved if all power was concentrated in one person: in an imperfect world, government by a single ruler was the best solution for a country in discord.

The success of the revolt of the Dutch United Provinces against imperial Spain helped to stimulate interest in Tacitus and his respect for Germanic peoples and heroes such as the German Arminius and the British Caractacus who had tried to resist the might of imperial Rome. The Dutch scholar Isaac Dorislaus was invited to be the first Professor of Ancient History at Cambridge in 1627, and gave two lectures on Tacitus. He drew alarming parallels with contemporary politics, suggesting that even in the Roman Empire sovereignty rested ultimately with the people and the absolutist claims of tyrannical emperors were illegitimate. The England of Charles I was not ready for such teaching: he was not allowed to finish the course of lectures. The full extent of his Tacitean radicalism became apparent in 1649 when he took part in the prosecution of Charles I which led to his execution. He was murdered by British royalists in the Hague on his return to his own country (Mellor, 2004).

Radical or 'red' Tacitism may subsequently have had a rather underground existence in England. But in his *Discourses concerning Government* (3.9) Algernon Sidney, champion of English republicanism, invoked Tacitus and his condemnation of the bad Roman emperors such as Nero 'and the rabble of succeeding monsters' as part of his argument against Robert Filmer's extreme monarchism in *Patriarcha*.

A generation later, Thomas Gordon, author with John Trenchard of the strenuously Whiggish *Cato's Letters or Essays on Liberty* (1720–23), drew on Sidney and on Tacitus, Livy, and Cicero in defense of freedoms of speech and warnings against the natural encroachments of power. Gordon devoted many years to a translation of *The Works of Tacitus* (1728–32), dedicated to Sir Robert Walpole, with various prefatory discourses critical of arbitrary power and empires ancient and modern, Roman, Turkish, and Spanish.

Classical Empire

Despite republican and Tacitean resistance to autocratic imperialism, the grandeur and longevity of the Roman Empire and the poetic anticipation and celebration of it in Virgil's *Aeneid* were influential in succeeding ages of colonial expansion and European empire-building. By the middle of the sixteenth century, the Portuguese had somehow contrived to acquire a fragile overseas empire stretching across the world from Brazil to Japan. The poet Luis Vaz de Camoens celebrated this achievement in his Virgilian epic *The Lusiads* (1572) which begins by inviting comparisons with classical adventurers overseas such as Virgil's Aeneas and the famous victories of the emperors Alexander and Trajan before settling down to epic celebration not of a single hero but of a whole race of them. Spanish imperial adventures and the Spanish Empire, at its height in the reign of Philip II (1556–98), had been sharply criticized by the Tacitean Thomas Gordon, but attracted Virgilian epic celebration in Alonso de Ercilla's *Araucana* (1569–89) which engages with the suppression of a revolt by Araucano Indians and the Spanish capture of a small valley in Chile (Quint, 1993: pp. 155–157). The successful Dutch revolt against Spanish rule facilitated seventeenth-century mercantile triumphs. This era stimulated writers such as the dramatist and national poet Joost van den Vondel (1587–1679) who hailed it in Virgilian terms (*Eclogue* 4) as a return to the Golden Age of classical mythology. But in 'Aen de Beurs van Amsterdam', his poem addressed to the immensely successful Amsterdam Stock Exchange, his allusion to Virgil's Dido and ruined Carthage, another great trading nation, hinted that such good fortune might not be permanent (Schenkeveld, 1991). Carthage, ultimately defeated by the Romans, was also associated with Britain, a mere nation of shopkeepers to the French who tended to see themselves in more heroic terms as modern Romans. Virgil was a useful starting for dreams of nation-building against the odds. As far away as the Ukraine Ivan Kotliarevsky burlesqued the *Aeneid* in his *Eneïda* (1798–1820), which links Aeneas and his defeated Trojan followers, ancestors of the imperial Romans, with the Zaporozhian Cossacks forcibly disbanded by Catherine the Great in 1775.

Victorian and Edwardian Britain, conscious of imperial hopes, glories and responsibilities, was also disposed to consider possible Roman parallels, though Edward Gibbon's endlessly reprinted *Decline and Fall of the Roman Empire* (1776–88) was a powerful reminder that even the most celebrated of empires eventually disintegrated. The Earl of Cromer, retired from colonial administration in Egypt, addressed the Classical Association on the subject of *Ancient and Modern Imperialism* (published in book form in 1910) and Sir Charles Lucas wrote thoughtfully about *Greater Rome and Greater Britain* (1912). But the parallels were not exact and uncomfortable aspects of the Roman experience such as overextension, corrupting luxury, and slavery, and unavoidable reliance on military force, were as much a warning as an inspiration.

The legacy of classical empire had always been tricky and ambiguous. The early church developed and spread within the Roman Empire and benefited from its communication systems. But it also suffered intermittent persecution, encouraging a certain caution. Early church fathers such as Tertullian, Irenaeus, and Origen prudently praised the stability, unity, and tolerance of the Roman empire (apart from a few persecutions under Nero and Domitian) and the fabled 'peace of Augustus', the *pax Romana* particularly associated with the emperor Augustus, seeing them as enabling conditions for the development of Christianity; Christianity in its turn, it was argued, had been a blessing to the empire, despite occasional calumnies against it. Augustine was much more critical in *The City of God*, written between 413 and 426 as the empire was crumbling, and so was the Spanish historian Orosius, whose *History against the Pagans* (417), written at Augustine's request, was the standard history of the ancient world available to the Middle Ages. But, even though Dante defended the Roman Empire as a model of government in his *Monarchia*, he was still content to follow Augustine and Orosius up to a point, endorsing their moral critique of the violent and tyrannical exercise of power. This is a theme in the *Inferno*, which places Alexander the Great among the Violent in the Seventh Circle of Hell, but Dante uncouples the violence of rulers from the imperial context which often sanctioned it. This partly ignores the informal moral and religious tradition stemming from Tacitus and Augustine which condemned military despotism and territorial aggrandizement and provided ammunition for later political commentators critical of aggressive imperialism in theory or in practice (Vance, 2011). There were formidable challenges to be negotiated by rhetorical champions of modern empire.

Benjamin Disraeli, novelist, fantasist, and spell-binding political orator, British Prime Minister in 1868 and again from 1874 to 1880, was just such a champion. In the 1870s he made political capital out of explicitly identifying Britain as a great imperial country and annexing the classical slogan *Imperium et Libertas* which he rather vaguely attributed to a great but unspecified Roman. The phrase was enthusiastically adopted as a motto by the Conservative Primrose League, founded in 1883, numbering over a million members at its peak and committed to maintaining the 'imperial ascendancy of the British Empire'. It can be traced back to Tacitus (*Agricola* 3) or possibly Cicero (*Philippics* 3.37), but it had long been misquoted and taken out of context. Though it was often translated as 'Empire and Liberty' Tacitus and Cicero had not intended to praise Empire as such but to draw attention to a seldom-resolved tension at the very heart of power politics: the need to uphold the rule of law without endangering civil freedoms (Hammond, 1963). Liberals such as W.E. Gladstone, Disraeli's great parliamentary opponent, four times Prime Minister, were not at all sure about empire, particularly empire on the grand scale as Disraeli imagined it. Gladstone was a more accomplished classicist than Disraeli and had read St Augustine as well as Tacitus and Cicero. He knew enough about Roman imperial history to be deeply worried about unchecked territorial acquisition. In speech after speech

in the 1870s he insisted that revival of the Roman imperial analogy, applied to contemporary adventures in Africa or Afghanistan, was morally and practically indefensible. No people, whatever their state of civilization, deserved to be subjected to military aggression to extend an overseas empire.

City and Satire

Theorizing and praising republican constitutions and city states was all very well, but actually living in the overcrowded cities of the ancient world such as Rome or Alexandria was often unpleasant. Greek and Latin pastoral poetry, much imitated in the vernacular literature of early modern Europe, had idealized the countryside and the lives of shepherds and country people to point a contrast with city life. Verse satire, harsher and darker, a Roman rather than a Greek literary form, took the critique of urban life and of public and private morals to much greater extremes. 'Imitations' or adaptations of Roman satirists such as Juvenal subjected aspects of the life of Paris or London to classical scorn. Nicholas Boileau's updated imitations of classical satire (1660–1708) enjoyed a considerable vogue in France. Samuel Johnson's poems 'London' (1738) and 'The Vanity of Human Wishes' (1749) are self-conscious imitations of Juvenal. Eighteenth-century Russia, influenced by the language and culture of France and encouraged by Peter the Great to be more receptive to western influences, turned to classical satire as mediated by the French as a new literary form. Prince Antiokh Kantemir (1709–44), pioneer Russian satirist and philosopher, Russian ambassador in London and then in Paris, wrote nine satires modeled on Horace and Boileau, first published in French translation and published in Russian only in 1762. He also translated Horace into Russian verse. He was one of the first Russian thinkers to invoke the metaphor of 'Liberty' as a heavenly goddess, as enshrined in the temple of Libertas on the Aventine Hill in Rome.

There was often a strong satirical component in classically influenced Utopian literature lampooning not just the politics but the intellectual and social fashions of the day. Fantastic imaginary voyages to the moon or the Isles of the Blest, as described by Lucian in the ancient world mingled with parodies of contemporary travels and voyage narratives to transport the reader to the surreal, black-comic invented worlds of François Rabelais' *Pantagruel* (1532) and *Gargantua*, (1534–35), Jonathan Swift's *Gulliver's Travels* (1726), and Voltaire's *Candide* (1759). In eighteenth-century Russia several utopian novelists followed the example of Lucian in colonizing the moon for satirical purposes. Mikhail Kheraskov's novels such as *Numa, or Flourishing Rome* (1768) described a utopian land curiously resembling his own country as a way of praising the Russia of Catherine the Great. On the other hand Prince M.M. Shcherbatov's *Journey to the Land of Ophir* (1783–84) uses his imaginary city of Peregab (Petersburg) to denounce Peter the Great's Westernization of Russia.

Plato to Popper

Plato was read in nineteenth-century Russia as well as everywhere else. His *Republic* included extended discussion of the education of the true philosophers who would alone be fit to be the Guardians or magistrates of the ideal state. With substantial supplementation from Cicero, particularly the *De officiis*, this contributed to recurring Renaissance considerations of the education of the prince or public official, such as Erasmus's *Education of a Christian Prince* (1516), Castiglione's much-translated *Book of the Courtier* (1528), and Thomas Elyot's *Boke named the Governour* (1531). Juan Luis Vives' *Declamationes Sullanae* (1520) approached the question of political leadership from another direction, presenting a fictional and rhetorical expansion of an actual historical situation by writing speeches for the Roman dictator Sulla which addressed questions of political principle and alleged political necessity. Plato's *Republic* also contributed to the construction of Thomas More's imaginary state in *Utopia* (1516) and, usually more indirectly, to the making of the countless utopian fictions that followed it.

Platonism and the quasi–religious, even mystical, Neoplatonism associated with the *Enneads* of Plotinus (*c*.205–270) had considerable influence on the development of religious thought in the early church and among the Cambridge Platonists in seventeenth-century England. It also influenced poetry and painting, particularly in renaissance Italy and in France. But it was not really until the nineteenth century that serious interest in Plato himself significantly revived among social and political thinkers. The legal reformer Jeremy Bentham had called him 'the master manufacturer of nonsense' in his posthumously published *Deontology* (1834), but (Demetriou, 2011) he was carefully studied by the Benthamite banker, politician, and historian George Grote, author of *Plato and the other Companions of Sokrates* (1865). John Stuart Mill, who was taught Greek at the age of three by his father in order to enable him to read Plato, admired his approach to truth through critical discussion rather than dogmatic assertion and reread the dialogues in order to review Grote's work.

Friedrich Hegel, convinced that reality itself was essentially dialectical, had responded positively to Plato's dialectical method, discussed also by the later Hegelian Herbert Marcuse in his *Reason and Revolution* (1941). The growing popularity of Hegelian idealism, particularly in nineteenth-century Oxford, encouraged renewed attention to Plato, translated by Benjamin Jowett of Balliol College who described Plato as the father of idealism. Plato was studied and cited by John Ruskin and others in support of late-Victorian moves to rethink the nature of the British state and state responsibility for its citizens.

There was something of a reaction against Plato in the twentieth century, though that could be seen more as reaction against totalitarian appropriations of Plato. In *Plato Today* (1937) the young Oxford tutor Richard Crossman, subsequently a senior figure in the British Labor Party and a Cabinet Minister, represented Plato as sharply critical of the political uses to which he had been put by Nazi and communist ideologues. After the Second World War, Karl Popper devoted the first volume of his *Open Society and Its Enemies* (1945) to attacking a repressively authoritarian version of Plato, though the main enemy was really Hegel rather than Plato (Bamborough, 1962).

Stoicism and Epicureanism

Christianity, influenced by Platonism, was also quite kind to the pre-Christian Stoic tradition stemming from the teaching of

Zeno of Citium (*c*.333–262 BC), particularly as it was represented by Seneca and, to a lesser extent, Epictetus. The rather grim determinism of Ecclesiastes in the Old Testament had a certain affinity with Stoic teaching though direct influence is unlikely. Seneca's brother is mentioned in the New Testament and Seneca and St Paul were contemporaries. The alleged correspondence between Seneca and St Paul, apparently accepted as genuine by Augustine and by Jerome, who thought it indicated that Seneca was a Christian, turned out to be a forgery, but there were some broad similarities in their beliefs. While Stoicism was never fully endorsed by Christianity, church fathers such as Tertullian and Augustine were attracted to aspects of it. The medieval philosopher and theologian Peter Abelard (1079–1143) was interested in Stoic ethics, particularly in his *Dialogus inter Philosophum, Judaeum et Christianum*. In the fourteenth century the Italian humanist Petrarch drew mainly on Seneca and Cicero for his *De Remediis Utrisque Fortunae*, a collection of philosophical dialogues arguing for Stoic calm. The English translation of 1579 was entitled *Phisicke against Fortune, as well prosperous as adverse*. In the sixteenth century John Calvin was a close student of Seneca and in his *Institutes* (3.8.9) tried to make a perhaps oversubtle distinction between Stoic *apatheia*, impassivity or willed indifference to suffering, and the Christian virtue of heroic endurance of God-sent suffering. The Dutch scholar Justus Lipsius' Stoic dialogues *De Constantia* (1584), the more popular French account of Stoic moral philosophy from the same period by Guillaume Du Vair, Bishop of Lisieux and Francisco de Quevedo's translation of Epictetus into Spanish (1635) as well as his own *Doctrina Estoica* (1635) all testify to enthusiastic neo-Stoicism in the early modern period (Morford, 1991). But this produced its own reaction. The materialism and extreme determinism associated with Stoicism alienated some Christian thinkers, all the more as the ever-controversial Spinoza had drawn on the Stoics for his view that true freedom could be found in reconciling oneself to the necessities of nature. In the *Encyclopédie*, Diderot prised Stoicism away from Christianity altogether by deeming it to be materialist, fatalist, and atheist. Seneca's reputation as a moral teacher suffered increasingly from his association with his former pupil Nero, but Seneca still commended himself to Ralph Waldo Emerson and American Transcendentalism in nineteenth-century America and the uncompromising moral teaching of Stoicism appealed to Victorian religious doubters such as Matthew Arnold anxious to cling on to morality without the metaphysical support of theology.

Epicureanism, the ancient rival concept of Stoicism, had a less distinctive afterlife as it was often misperceived as mere pleasure-seeking and did not commend itself to austere Christian moralists. Epicurus (341–279 BC) had been an influential teacher in Athens but very little has survived of his writings. Epicurean teaching and the atomic theory which Epicurus had adapted from Democritus have come down to us largely through Lucretius' didactic poem *De Rerum Natura*, known in antiquity but largely forgotten in the Middle Ages, rediscovered in the fifteenth century. Lucretius, imaginatively as well as intellectually committed to the beauties, energies, and intricate workings of the material universe, was variously respected as a scientific theorist and a nature poet, particularly in the increasingly scientific eighteenth century. He had assigned a purely nominal role to the gods, argued for human free will and attacked theological views of the world and the needless misery caused by religious superstition, which endeared him to freethinkers from Giordano Bruno to Percy Bysshe Shelley even if it angered theologians such as John Calvin. He featured prominently in the doctoral thesis of Karl Marx (1841) on the difference between the Democritean and Epicurean philosophy of nature, attributing to Epicurus an assertion of absolute freedom of spirit. Lucretius (5.113-25) had criticized the appalling punishment the gods gave to rebellious Titans such as Prometheus, comparing them with ground-breaking thinkers more generally, and this encouraged Marx's enduring admiration for Prometheus as the archetypal rebel-hero (Megill, 2002: pp. 75–76).

Anthropology and Psychoanalysis

Classical studies could provide sources and examples for new sciences. Classical authors and classical archaeology provided evidence, of disputed reliability and significance, about long-forgotten ancient cultures and cultic practices. The Greek historian Herodotus, often acclaimed as the 'father of history', acquired a new reputation in the nineteenth century as the 'father of anthropology'. His traveler's observant curiosity about local customs and traditions in Egypt and elsewhere anticipated that of Tacitus in Germany or the Greek geographer Pausanias in different parts of Greece many centuries later (Elsner, 2010). Pioneer scholars of primitive customs and cultures such as E.B. Tylor (1832–1917), first Professor of Anthropology at Oxford, needed to range widely across time and space to collect and compare their evidence, and Herodotus and Tacitus were useful early observers. Myth and legend preserved in very ancient sources such as Homer's epic narratives or Hesiod's systematic accounts of the gods of Greece in his *Theogony* could also be pressed into service and accommodated to larger theoretical structures. The fourteenth-century French *Ovide moralisé* was just one of many attempts, some going back to the early church fathers, to read classical mythology as coded religious and moral discourse, perhaps as versions or variants of biblical story, so that the mighty Hercules was claimed as a version of the Old Testament Samson and Deucalion's flood in Ovid's *Metamorphoses* was interpreted as a muddled recollection of Noah's flood in Genesis. Eighteenth-century freethinkers and Deists wondered whether all ancient myths reflected some underlying system of religious belief (Kuhn, 1956). Classical and biblical story both fed into Jacob Bryant's eccentrically syncretist *New System, or, an Analysis of Ancient Mythology* (1774–76), but (Blok, 1994) speculative work of this kind gradually yielded to attempts at a more rigorously scientific approach, notably by the German scholar Karl Ötfried Müller (1797–1840). Yet speculation was not dead: Tylor in *Primitive Culture* (1871) considered that the Greek stories of Odysseus or Orpheus going down into the underworld could be interpreted as solar myth, a departure at the end of day into a dark unknown, and noted there were comparable stories in other cultures, Polynesian, Scandinavian, and native American.

As Tylor acknowledged, alleged solar myths in classical and other sources, mocked and parodied even in their Victorian heyday, were particularly associated with the work of the

great Sanskrit scholar Friedrich Max Müller (1823–1900), a comparative philologist particularly interested in Indo-European languages and belief-systems. His philological approach was challenged by his arch-rival, the classical scholar, translator, poet, and polymath Andrew Lang (1844–1912), but Lang's much-reprinted *Custom and Myth* (1884), dedicated to Tylor, and other works such as *Myth, Ritual and Religion* (1887), again make use of classical materials, particularly Homer, Hesiod and Herodotus. Classical sources are also important in J.G. Frazer's massively ambitious comparative anthropological study of magic and religion, *The Golden Bough*. Between the first edition (1890) and the greatly expanded third edition (1911–15) he published a substantial anthropologically enriched edition of Pausanias in 1898. Frazer provided a starting-point for the so-called Cambridge Ritualists such as the classical scholars Jane Harrison (1850–1928) and Gilbert Murray (1866–1957) who tried to use anthropology and the study of ancient fertility rituals to elucidate ancient Greek culture and the origins of tragedy, a topic already approached in more speculative form in Friedrich Nietzsche's *The Birth of Tragedy* (1872). Frazer, like Karl Marx with Prometheus, encouraged symbolic readings of classical myth and legend. Sigmund Freud's 'Oedipus complex', first proposed in 1909, used the story of Oedipus murdering his father and marrying his mother in Sophoclean tragedy to universalize his famous theory of male psychosexual development (Leonard, 2013). Carl Jung, aware that in tragedies by Sophocles and Euripides Electra had killed her mother Clytemnestra, suggested a corresponding 'Electra complex' as an aspect of female psychosexual development in 1913, but Freud was unimpressed (Dervin, 1998). In a late essay, posthumously published in 1963, the psychiatrist Melanie Klein, influenced by Gilbert Murray's translation of Aeschylus' *Oresteia*, used the ancient legend of Agamemnon and his family, the doomed house of Atreus, to illustrate her views on fear, guilt, aggression, and hatred in the family (Alford, 1990).

The Classics and the Moderns

Classical literature continues to be a familiar reference-point in modern thought. In the second part of *Dialectic of the Enlightenment* (1947), Max Horkheimer and Theodor Adorno claimed the adventures of Homer's Odysseus by land and sea enacted the struggle for self-preservation and autonomy and the development of human subjectivity through repression and sacrifice and resistance to the primal forces of nature. Derrida's 'Plato's Pharmacy' (1968) and Ronald Dworkin (Dworkin, 2011) show new arguments about meanings and morals can still involve rereadings or invocations of Plato and Aristotle. The Aristotelian distinction between *techne* ('craft' or 'art') and *praxis* ('acting') (*Nicomachean Ethics* 1.1) is harnessed to critical social theory in Jurgen Habermas's *Theorie und Praxis* (*Theory and Practice*) (1973). Martin Heidegger's radical interrogation of the nature of Being in *Being and Time* (1927) begins by invoking Plato's *Sophist* and *Parmenides* and Aristotle's *Metaphysics* on the subject. But in attempting to probe deeper he pushes his enquiries further back in time, like Husserl before him, to the enigmatic fragments of relatively neglected pre-Socratic Greek philosophers, particularly Parmenides and Heraclitus, on whom he lectured in the 1940s and 1950s. He makes use of Parmenides' innovative attempt to deduce the character of what is from the requirements of thought and language and Heraclitus' celebration of constant flux and disturbance as the due and necessary order of things. His concerns with Phenomenology and with Truth leaned hard on the etymologies of the underlying Greek terms, associating 'phenomenon' with light (*phos*) to bring out the meaning of that which lies in the light of day or can be brought to light. The Greek term *aletheia*, usually translated 'truth', is the formal opposite of *lethe*, 'forgetfulness' or 'oblivion', what escapes notice, which enables an understanding of truth as something like 'unconcealedness'. Greek terminology and this etymological method have proved useful to others. Giorgio Agamben, who had attended some of Heidegger's seminars, discussed the Greek terms *poiesis* and *praxis*, 'making' and 'acting', in *The Man without Content* (1999), expanding on the distinction Aristotle makes between them (*Nicomachean Ethics* 6.4) by distinguishing between artistic or creative production on the one hand and action or immediate practical expression of the will on the other. It seems likely that contemporary thinkers will continue to exploit their classical legacy.

Classical Mechanics and Motor Control

Pietro G Morasso, Istituto Italiano di Tecnologia, Genoa, Italy

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by S. Mussa-Ivaldi, volume 3, pp. 1951–1955, © 2001, Elsevier Ltd.

Abstract

The article analyzes the application of basic principles of classical mechanics to the human body, namely biomechanics. The multireferential nature of the human movements is emphasized, considering the multiplicity of 'motor spaces' that describe human motion: tool space, end-effector space, joint space, and muscle space. In this framework, coordinate transformations and kinematics are analyzed, taking into account the causality constraint in the development of descriptive models, namely well-posed transformations from one kinematic descriptor to another in spite of the global redundancy of the motor system. Using the Lagrangian formalism, we derive the dynamic equation of a kinematic chain, which may model a human upper or lower limb. The complexity of the dynamics is considered, with emphasis on nonlinearity and anisotropy of the different dynamic components: inertial forces, Coriolis forces, gravity forces, external force fields, and muscle forces. The question is formulated about the necessity, for the brain, to be a 'conscious' expert of such mechanical complexity. Tentative answers are suggested while outlining a range of control schemes that are known in the repertoire of the motor control system: feed-forward, model-based control; stiffness control; and feedback control. As regards the last class of control mechanisms, the critical influence of delayed sensory afferences is taken into account, showing how intermittent, event-driven control in many situations may be more robust and more biologically plausible than classical, continuous-time feedback control.

As a physical system made of flesh and bones, the moving human body can be described in terms of classical mechanics. This concept is captured by the term 'biomechanics,' which deals with the relative and global motions of different body parts, the forces and moments transmitted by the muscles, as well as the associated flows of energy. The first scientist to address the study of the moving human body in this framework was Giovanni Alfonso Borrelli (De Motu Animalium, 1680) who applied to human physiology the mechanical concepts and formalisms developed by Galileo Galilei a few decades before. However, this is only part of the story, because goal-oriented coordination of the different body parts requires the brain, which is interfaced with the body in a bidirectional manner through muscle actuators and multimodal sensory channels (see Motor Control Models: Learning and Performance). The question then arises to which extent the brain must be and/or is fully aware of the complexity of biomechanical dynamics. Biology indeed provides a large number of examples, such as insects, where neural control is extremely simplified, in face of a very complex dynamics of the insect's body.

In fact, there is a range of possible answers, supported by a variety of experimental and theoretical evidence. On one extreme it is suggested that the brain develops internal representations of the mechanics of the body coupled with its environment (internal models Wolpert and Kawato, 1998; Kawato, 1999) through a process of motor learning, thus becoming implicitly an 'expert' in classical mechanics. On the opposite extreme there are examples of how purely reactive natural or artificial agents–agents that have no internal states but only direct connections between sensors and motors–can exhibit complex, adaptive behaviors. Consider, for example, the *Aplysia depilans* (Kandel and Tauc, 1965) or the vehicles of Valentino Braitenberg (1986). In the realm of artificial intelligence, Rodney Brooks (1986) introduced a computational framework (subsumption architecture) based on decentralized control and generalized the concept by proposing the idea of "intelligence without representation" (Brooks, 1991).

Moreover, even if one accepts the hypothesis that the brain is an expert in the mechanics of its own body, it still remains unclear where is the focus of the supposed internal models used by the motor controller. In much of the literature, it is taken for granted that 'internal models' means 'internal models of limb dynamics,' with the underlying assumption that dynamics is the most fundamental building block in the neural control of movements. However, this hypothesis is challenged by recent evidence in motor imagery made available by advanced techniques of brain imaging. It appears indeed that the brain activity recorded during imagined movements ('motionless' motor actions) is quite similar to the activity of actual movements, except for the specific muscle activation patterns conveyed in the final common pathway of the motor controller (Jeannerod, 2001; Kranczioch et al., 2009; Munzert et al., 2009). This suggests that although dynamics is likely to play an important role in motor control, on top of it there is a computational layer that deals with 'synergy formation' independently of forces and masses that are experienced only during real, overt movements.

Synergy Formations: Motor Redundancy, Coordinate Systems, and Kinematics

A significant computational challenge for the brain comes from the need to perform changes of representation – or more technically, coordinate transformations – between the description of a task and the specification of the body motions. Tasks, such as hitting a ball with a racket, are described most efficiently and parsimoniously with respect to some fixed reference points in the environment (frequently called' endpoint'). In the example, the racket is the site at which one interacts with the environment. The position of the racket

is fully determined by six coordinates. These coordinates may be measured with respect to three orthogonal axes originating, for example, from the shoulder. Then, a position in endpoint coordinates may be specified as a point $\vec{p} = (x, y, z, \theta_x, \theta_y, \theta_z)$ in six dimensions. The subset of coordinates (x, y, z) determines a translation with respect to the orthogonal axes; the other subset of angular coordinates $(\theta_x, \theta_y, \theta_z)$ determines an orientation with respect to the same axes. Consistent with this notation, a force in endpoint coordinates, for example originating from the interaction of the racket with a ball, is a vector with three linear and three angular components, $\vec{F} = (F_x, F_y, F_z, \tau_x, \tau_y, \tau_z)$.

A different way of describing the position of an arm is to provide the set of joint angles that define the orientation of each skeletal segment either with respect to fixed axes in space or with respect to each other. Joint angles are a particular instance of generalized coordinates. According to the standard definitions of analytical mechanics, generalized coordinates or degrees of freedom (DoF) are independent variables, which are suitable for describing the kinematic and dynamics of a system (see, for example, Goldstein, 1980). Once we have defined a set of generalized coordinates, we may also define a set of corresponding generalized forces. For example, if we use joint angles as generalized coordinates $\vec{q} = (q_1, q_2, \ldots, q_n)$, the corresponding generalized forces are the torques generated at each joint $\vec{\tau} = (\tau_1, \tau_2, \ldots, \tau_n)$; n is the number of DoFs.

Movements are executed by the central nervous system activating a multitude of muscles. The motor system is indeed highly redundant at least at two levels: the number of DoF is much greater than the number of variables that describe a task, and the number of muscles is much greater than the number of DoF. Moreover, muscles are composed of a large number of motor units (collections of motor fibers innervated by the same motor neuron) and their activation patterns have some degree of independence, although the overall recruitment process is characterized by Hennemann size principle (Henneman et al., 1965). This means that each task-oriented action can be conceived, imagined, coordinated, and activated in an infinite number of ways. In spite of this, and on top of an intrinsic variability that characterizes even the most practiced skills, the observed motor patterns, at both kinematic and muscular levels can be described by a small number of components, somehow correlated with the relevant task variables.

In general, we may say that coordination of movements or synergy formation is a multireferential problem that involves multiple 'spaces' at the same time: task space, end-effector space, joint space, and muscle space. The dimensionality of the spaces grows from the task space to the joint and muscle spaces, and such dimensionality imbalance is the source of what is known as motor redundancy. In each space we can identify motion variables and effort variables. Causality, in the sense of well-posed nonlinear mappings, runs in opposite directions as regards movement and effort:

- Joint space → End-effector space → Task space (motion variables)
- Task space → End-effector space → Joint space (effort variables)

This means, for example, that an elementary joint rotation pattern can be uniquely mapped into an elementary motion of the end-effector and then into a motion in the task space (for example, the motion of a handheld tool). In contrast, an effort applied by means of a tool in task space can be uniquely mapped into an effort of the end-effector, and then an effort of the joints. The latter causal chain can be considered an inverse model because it makes it possible to compute the effort that is needed for obtaining a desired effect at the end of the kinematic chain; the former chain is a direct model, in the sense that it makes it possible to predict the task-relevant consequence of delivering a coordinated motor pattern. A pair of direct/inverse models is considered 'inseparable twins' for skilled motor control (Kawato and Wolpert, 1998). More technically, the transformations quoted above can be expressed by means of the Jacobian matrices of the corresponding nonlinear mappings:

$$\begin{cases} dq_j \rightarrow dp_e = J_j\, dq_j \rightarrow dp_t = J_t\, dp_e \\ df_t \rightarrow df_e = J_t^T\, df_t \rightarrow d\tau_j = J_j^T df_e \end{cases} \quad [1]$$

where dq_j is an elementary motion in the joint space, dp_e is the corresponding motion in the endpoint space, and dp_t is the motion in the tool space. J_j, J_t are the two Jacobian matrices that describe the mappings between the joint/endpoint space and the endpoint/tool space, respectively. τ_j, f_e, f_t represent the corresponding efforts. The 'T' symbol implies that the corresponding matrix is 'transposed' (the rows are exchanged with the columns), and this is required by the duality between effort and motion and the fact that work is an invariant when passing from one space to the other.

Some experimental studies (see Morasso, 1981; Flash and Hogan, 1985) have suggested that actions are planned by the brain in terms of endpoint coordinates. For example, one can mentally formulate (and execute) commands such as "move the hand 10 cm to the right" without being concerned with the set of muscle commands that are involved with this action. However, once one has decided a plan of action, one must somehow choose how to coordinate the joint rotations, which muscles to activate, and in what temporal order. The latter part of the plan (generation of muscle synergies) is only operant in overt movements, whereas the former part (generation of joint synergies) must be operant both in covert and overt actions.

Dynamics

The well-known Newton's equation ($\vec{F} = m\,\vec{a}$) tells us that a point mass (i.e., a point of negligible size and with a mass m) will accelerate when a force vector is applied to it, with an acceleration magnitude that is directly proportional to the force and inversely proportional to the mass. Such a statement expresses the direct dynamic problem: from the cause (the applied force) to the effect (the acceleration and, ultimately, the actual motion by integrating the differential equation). Moreover, the same equation can be read in the opposite direction, expressing the inverse dynamic problem: from the desired motion (the time course of the acceleration vector) to the required effort (the time course of the applied force).

If the object's size is not negligible, force vectors can be applied to many points of the object (for example, many

muscles can apply forces to different parts of the same bone); in this case, Newton's equation is split into two components, one related to the motion of the center of mass (CoM) of the object and the other to the rotation around an axis through the CoM:

$$\begin{cases} \vec{F}_{\mathrm{R}} = m\dfrac{\mathrm{d}\vec{v}}{\mathrm{d}t} \\ \vec{M}_{\mathrm{R}} = I\dfrac{\mathrm{d}\vec{\omega}}{\mathrm{d}t} \end{cases} \qquad [2]$$

Here $\vec{F}_{\mathrm{R}}$ is the resultant vector of all the forces applied to the object; $\vec{M}_{\mathrm{R}}$ is the resultant moment; $\vec{v}$ is the velocity vector of the CoM; and $\vec{\omega}$ is the angular velocity of the object. The human body is usually modeled as a set of linked rigid bodies, one for each body part. For example, a limb like the arm can be modeled as a kinematic chain with three links, namely the humerus, the forearm, and the hand, and several DoF. The dynamic equations of such a system can be derived by generalizing the cardinal equations above, that is, by writing the pair of equations for each body segment and taking into account the constraints introduced by the joints. This is the so-called Newton–Euler recursive algorithm, which makes it possible to derive the distribution of forces in a kinematic chain given precise measurements of the kinematics (joint angles, angular velocities, and accelerations) and the endpoint forces. It is an efficient algorithm of dynamic computation, typically used in gait analysis, but is somehow difficult to interpret.

A more compact form is provided by the Lagrangian formalism, which focuses on energy rather than force. For any complex dynamic system, with scleronomous constraints (constraints in which time is not an explicit variable), the following Lagrangian function can be defined: $L(q,\dot{q}) = K(q,\dot{q}) - P(q)$, where K is the kinetic energy and P the potential energy possessed by the system at any given instant of time. Both elements of the Lagrangian function have an additive property, that is, they are computed by adding the kinetic and potential energies of each link, respectively. The dynamics of the kinematic chain can then be represented in a compact way by the following equation:

$$\tau_m = I(q)\ddot{q} + C(q,\dot{q})\dot{q} + G(q) + J_{\mathrm{e}}^{T}F_{\mathrm{e}} \qquad [3]$$

The n-dimensional vector on the left-hand side of the equation is the set of torques (or generalized forces) that must be applied to the joints in order to realize a given law of motion, that is, a given time course of the joint rotations $q = q(t)$. The joint torque vector is determined by the activation of the actuators that control the kinematic chain, namely the muscles in the biological case. The equation says that such actuator forces must take into account four contributions: (1) inertial forces, proportional to acceleration ($I(q)$ is the $n \times n$ inertial matrix of the kinematic chain); (2) Coriolis forces, proportional to angular velocity; (3) gravity forces, which only depend on position; and (4) external forces (if the kinematic chain interacts with the environment through the end-effector, otherwise this contribution is null). In discrete, point-to-point movements, where speed is generally bell-shaped (Morasso, 1981), inertial forces are predominant in the initiation and termination phases, whereas Coriolis forces are predominant in midflight. For very slow movements (or in the case of imagined movements that do not involve any kinematic energy), inertial and Coriolis forces can be neglected and thus the brain can only focus on quasistatic elements: gravity and external forces.

The inertial matrix generally is not proportional to the identity matrix and this implies that the inertial properties are not isotropic but change with movement direction. The anisotropy of the matrix can be well illustrated in geometric terms if we consider the ellipsoid that relates a torque vector to the corresponding acceleration vector. This ellipsoid has a specific orientation in space and its major axes coincide with the eigenvectors of the matrix. In the case of the arm, it can be shown that the ellipsoid is oriented with its major axis approximately aligned with the forearm (Mussa-Ivaldi et al., 1985). This means that the 'apparent inertia' perceived by an external agent interacting with the subject's arm is not constant but varies with the direction of interaction and has a maximum value if the interaction direction is aligned with the subject's forearm. Another consequence of such inertia anisotropy is that in general if a force is applied to the end-effector, the resulting acceleration is not collinear but there is a deviation between force and acceleration, in contrast with the dynamics of the point mass.

Feed-Forward, Stiffness, and Feedback Control

The brain can affect the time course of vector τ_m in eqn [3] by selecting appropriate muscle activation patterns, according to a control scheme. In particular, we will briefly touch upon three main classes: feed-forward, feedback, and stiffness control schemes.

We should take into account that muscles are not pure force or torque actuators but have a complex internal dynamics that links chemical, electrical, and mechanical variables. Nonetheless, the three-element muscle model proposed by Hill (1938) is generally considered an acceptable approximation: it includes a nonlinear contractile element, a series, and a parallel elastic element. The essence is that muscles can generate force but with an intrinsic mechanical impedance. In particular, the elastic component of impedance, that is, stiffness, is a function of both muscle length and neural drive level. Moreover, we must take into account that muscles are arranged in antagonistic sets around the joints of the body: the forces of antagonist muscles are subtracted from each other, whereas the stiffness values are added. Therefore, the brain can choose reciprocal activation patterns if it is concerned with the production of torque around a joint, or coactivation patterns if it needs to affect the joint impedance. By properly tuning the two activation paradigms, the brain can control the torque τ_o delivered at the joints, the corresponding joint stiffness K_{j}, and the reference or equilibrium trajectory $q_o(t)$:

$$\tau_m = \tau_o + K_{\mathrm{j}}(q - q_o) \qquad [4]$$

τ_o, q_o, and K_{j} are functions of the neural drive and of the mechanical state of the body $(q, \dot{q})$. Therefore, the overall dynamics described by eqn [3] implies a bidirectional interaction between the neuromuscular system (left part of the equation) and the body–environment system (right part of the equation).

Suppose now that a movement must be produced with a desired law of motion $q = q_d(t)$. In principle, the brain can achieve the plan by means of three main control mechanisms:

1. *Feed-forward control*, based on an accurate internal model of the limb dynamics and/or external disturbances:

$$\begin{cases} q_o = q_d \\ \tau_o = I(q_d)\ddot{q}_d + C(q_d, \dot{q}_d)\dot{q}_d + G(q_d) + J_e^T F_e(q_d, \dot{q}_d) \\ \quad = \text{Model}(q_d, \dot{q}_d) \end{cases} \quad [5]$$

   In the ideal case, where the internal model is flawless and there is no noise, then applying feed-forward control will result in the actual movement $q(t)$ being identical to the planned one and the contribution to the overall dynamics of stiffness will be null. According to such a scheme, the brain generates neural commands in anticipation of the actual movement, on the basis of interacting neural networks that replicate the external dynamics of the body–environment system. Of course, it is not conceivable that such internal model is innate because the dynamics of the body–environment system is not constant but varies with age, loading conditions, and task-dependent environmental conditions. Therefore, internal models must be the result of a learning process. This has been and still is the subject of many studies, beginning with the seminal work of Kawato and Gomi (1992). Nonetheless, the acquired internal model will be only an approximation and there will be noise, thus causing a discrepancy between the planned and the real trajectory: $\Delta q(t) = q_d(t) - q(t)$. This is where joint stiffness comes into play, moderating the effect of noise and modeling error: $K_j\,\Delta q(t) = \Delta\text{Model}(q, \dot{q}) + \text{noise}$.

2. *Stiffness control*, based on a high level of coactivation. This control strategy does not require any internal model of the body–environment dynamics and regards such dynamics as a kind of disturbance or noise to be 'resisted' by muscle stiffness. This strategy is related to the equilibrium point hypothesis (Asatryan and Feldman, 1965; Feldman, 1966; Bizzi et al., 1976, 1991, 1992; Feldman and Levin, 1995), which assumes that in the control of movement the brain is only concerned with the equilibrium between internal and external force fields and compensates the disturbances due to dynamics by means of muscle stiffness. In order to be effective, the control scheme requires sufficiently high values of stiffness, and the question has been raised to which extent and/or in which conditions this can occur. Also in the case of the stiffness strategy, a learning process is required, because the brain must learn the stiffness values that are required in given conditions. However, this is much simpler than learning a full-blown internal model of body–environment dynamics. Also the run-time control is much more complex in feed-forward than in stiffness control: in the former case the brain must produce a very detailed profile of control signals, whereas in the latter it must simply 'stiffen up' to the required level before the movement start and then generate the equilibrium patterns. On the other hand, a stiffness strategy is energetically more expensive because it requires high coactivation levels.

3. *Feedback control*. Both feed-forward and stiffness control are open-loop strategies, which do not exploit the sensory feedback coming from proprioception or other types of receptors of body movement. In feedback control paradigms, the motor control commands originate from a comparison between ideal or reference values of body motion parameters and the actual values transmitted by the sensory channels, namely the explicit computation of a motor error signal. There are at least three different ways in which such error signals can be used by the neural controller: (1) reflex control, which reacts 'one-shot' to an unpredicted disturbance; (2) sustained, closed loop, continuous-time control, similar to engineering servomechanisms; and (3) intermittent, closed-loop control, such as the balancing actions in the manual stabilization of an inverted pendulum.

It is also possible to conceive mixed strategies. For example, feed-forward model-based control can compensate for only part of the dynamics, such as the static component due to gravity, which does not depend on the speed of the movement. In this case, stiffness control must compensate for only part of the unaccounted dynamics and a lower level of cocontraction is necessary.

Stiffness control is a kind of feedback control because the driving force is proportional to the mismatch between the planned and actual position of the different joints. However, in stiffness control the mismatch is not computed explicitly on the basis of feedback sensory signals, but implicitly by the viscoelastic properties of muscles. Therefore, it is an instantaneous feedback. Explicit feedback control, particularly in the case of continuous-time feedback, is affected by a major problem: feedback sensory signals are far from instantaneous. Summing up the propagation delay and the contraction delay in the segmental reflex loop, the functional delay is over 100 ms. In control engineering, it is well known that delays of this order of magnitude severely limit the frequency bandwidth and the feedback gain that can be used for compensating internal/external disturbances without triggering instability. Therefore, explicit feedback control tends to be a mechanism of last resort for unpredictable disturbances or for dynamic tasks that a subject did not have enough time to practice.

Evidence of Feed-Forward, Model-Based Control

Strong experimental evidence for the biological and behavioral relevance of internal models has been offered by experiments that involved the adaptation of arm movements to a perturbing force field generated by an instrumented manipulandum (Sabes et al., 1998; Shadmehr and Mussa-Ivaldi, 1994). This corresponds to the external force of eqn [3]. In order to investigate the possible emergence of feed-forward control, the external force must be deterministic and predictable but characterized by a dynamics which was completely unknown to the subjects. A typical example is a curl viscous field, which disturbs point-to-point reaching movements with a force which is proportional to the instantaneous speed and is directed perpendicularly to the direction of the speed vector. People are quite unlike to have experienced such kind of dynamics, which tends to

deviate sideways the movement to the target. Thus, in the initial exposure to the field only muscle stiffness operates in such a way to limit the entity of the motor error. However, with practice people can recover the original path and kinematics and consolidate such knowledge (Brashers-Krug et al., 1996). Since the movements are rather fast, at least in the first part there is no time for feedback to influence the mechanism that compensates the disturbing field. Therefore two possible explanations must be considered: stiffness control and feed-forward control. The former explanations can be ruled out for two reasons: (1) no evidence has been found of the cocontraction that would be required by a substantial increase of stiffness; (2) if the force field is unexpectedly turned off (catch trials) after the subject learned to compensate the disturbance, the trajectory is distorted in a mirror way with respect to the field. One would not expect such counterdeformation in the absence of disturbance if the subject was exploiting stiffness; in contrast, the recorded behavior is consistent with an anticipatory modification of the term $\tau_o(t)$ in eqns [3] and [4], incorporating the acquired knowledge of the disturbing field.

Evidence of Stiffness Control

Suppose that an instrumented manipulandum, similar to the one mentioned in the previous section, is programmed in such a way to generate a divergent force (DF) field during point-to-point reaching movements. If a subject moves along the ideal straight path with a bell-shaped speed profile in accordance with spontaneous human behavior, then the field is null. If the hand deviates laterally, the field pushes the hand sideways proportionally to the lateral error. In other words, the simulated dynamic environment is unstable.

The critical point is the relation between endpoint stiffness and the rate of growth of the DF, which is a kind of negative stiffness. Endpoint stiffness can be represented geometrically by means of an ellipsoid (or ellipse in the case of planar movements) in a similar way to the endpoint inertia of the arm. The difference is that the former ellipse can be modulated by neural activation patterns whereas the latter ellipse cannot be, for obvious physical reasons. The stiffness ellipse that can be recorded with spontaneous tonic activity of arm muscles is rather small and is oriented approximately with a polar pattern (i.e., is aligned with the line that joins the hand to the shoulder: Mussa-Ivaldi et al., 1985). If all the arm muscles increase proportionally their activity level with respect to the basis level, the ellipse size will increase without affecting its orientation. Rotation of the ellipse requires a more sophisticated rearrangement of the relative activation patterns of the muscles.

Coming back to the DF experiment, if the lateral rate of growth of the field is smaller than the lateral component of the stiffness ellipse in the spontaneous activity level of the muscles, then the destabilizing effect of the field will be compensated by the natural muscle stiffness, allowing the subject to reach the target, although with some error. However, if the DF is stronger than such critical value, the subject will 'fall' on one side or the other and will be unable to reach the target. Indeed this was found by Burdet et al. (2001), but they also found that subjects can learn to compensate for the instability after a suitable number of trials. In these experiments, no miscompensation was observed during catch trials, thus ruling out the possibility of a feed-forward compensation strategy. In contrast, it was found that in the course of learning the subjects managed to tune coactivation patterns of the muscles in such a way to obtain a stiffness ellipse of sufficient size and oriented optimally, namely aligned with the direction of instability. In other words, a stiffness strategy can be used by the brain in suitable experimental conditions and can be learned by human subjects.

Evidence of Intermittent Feedback Control

In the DF experiment described in the previous section, human subjects demonstrate that a stiffness strategy can be learned and applied for carrying out an unstable task. However, this is not a *universal* solution to tasks of this kind. There are unstable tasks where a stiffness strategy is impossible due to the nature of the task or the properties of human tissues. For example, when balancing an inverted pendulum placed on top of the hand's palm, subjects are unable to modify the stiffness of the pendulum virtual joint, which remains close to nil throughout experiments. Human upright standing can also be likened to an inverted pendulum. In this case, the ankle stiffness is not null and in principle can be modulated by coactivating the ankle muscles. But this is not what people do during quiet standing. The reason is that the Achilles tendon is too compliant (see Loram et al., 2005a for direct measurements of the tendon stiffness) in relation to both the toppling gravity torque and the range of stiffness values of the ankle plantar flexors. This is a quite peculiar situation, because in most sites of the human musculoskeletal system tendons, connecting muscle groups to bones, are much stiffer than the physiological range of muscle stiffness values. Considering that tendons and muscles are connected in a serial fashion, this makes it possible to modulate joint stiffness by coactivating antagonistic muscle groups. But this is not functional in the ankle case because the low stiffness of the tendons radically reduces the range of ankle stiffness values achievable by means of cocontraction.

As a consequence, in both situations sketched above, the stiffness strategy successfully adopted by human subjects in the DF experiments is ineffective and thus is ruled out by the subjects. What is observed, instead, is the presence of intermittent control patterns (Cabrera and Milton, 2002 in the human balancing task; Bottaro et al., 2005; Loram et al., 2005b in the upright standing synergy). Intermittent, closed-loop control should not be confused with sampled-data control, which is an engineering technique dictated by the use of digital computers in the control of dynamic processes. Rather, as concisely expressed by Gawthrop et al. (2011), the control mechanism is 'continuous observation, intermittent action.' In other terms, in intermittent control paradigms, a sensory observer is supposed to continuously analyze the flow of multimodal sensory signals in order to spot critical events and then to 'fire' at the right moment control bursts that temporarily stabilize the system. The crucial point is that even in unstable tasks it is possible to

single out in the state space stable and unstable manifolds that have different degrees of instability. Therefore, an event can be a situation in which the system state comes too close to an unstable manifold, requiring an urgent stabilizing action, or close enough to a stable manifold, suggesting that control signals turn off because intrinsic dynamics is sufficiently 'well behaved.' This kind of stabilization strategy is effective, even with delayed feedback, and indeed it has been demonstrated for upright standing that it is much more robust that a corresponding continuous-time control strategy, with the same value of delay in the feedback loop, in the sense that it can guarantee stability for a much larger range of drift/uncertainty of the control parameters (Asai et al., 2009; Suzuki et al., 2012).

Generally speaking, since the time of Woodworth (1899), it has been well known from the observation of rapid limb and eye movements that the human repertoire includes control mechanisms with a discrete, preprogrammed, ballistic nature that also includes some kind of psychological refractory period. Later on, the analysis of human operators in a loop that implies sustained, continuous feedback from some external process has prompted the emergence of explanations based on various forms of intermittent, predictive control (Craik, 1947; Bekey, 1962; Navas and Stark, 1968; Miall et al., 1993; Hanneton et al., 1997), challenging traditional engineering explanations based on continuous-time control. Apart from empirical aspects, such as the degree of data fitting, the rationale of favoring intermittent predictive over continuous predictive control in the biological domain is that the former control paradigm provides a simpler algorithm than the latter due to the very simple form of the predictor. However, as well explained by Gawthrop et al. (2011), intermittent control has a 'masquerading property,' which makes it indistinguishable from continuous control under some experimental conditions.

Concluding Remarks

Classical mechanics has certainly an important role to play in human motor control, but this role is mediated by the cybernetics of purposive actions that adapts control mechanisms to the nature of the task and the constraints imposed by the body and the environment. This implies a kind of hierarchy between geometric, kinematic, and dynamic aspects in the generation of purposive actions, in order to maintain a degree of uniformity between covert and overt actions. When it comes to carrying out overt actions, the main problem to face is the delay in the acquisition of sensory information about the ongoing action. A variety of control mechanisms have been developed for this purpose. At the lowest level, in the case of unpredicted disturbances, the intrinsic stiffness of muscles provides some zero-delay feedback, which may be insufficient but is supported, after some delay, by segmental reflexes. Thus muscle stiffness and segmental reflexes are synergistic in many cases.

If the source of internal/external disturbance is predictable, training can make it possible to develop internal models of the disturbances that can drive a feed-forward control mechanism. Again, error models and/or additional sources of noise can be partially compensated for by muscle stiffness and reflexes.

In some case, as in the DF experiments, the detailed time course of the disturbance cannot be the predicted and/or learned but some global parameters can be acquired during training, such as the range and directionality of the disturbance. This is enough for the brain to program an optimal muscle coactivation pattern that implements predictive stiffness control. This mechanism is a combination of feed-forward and feedback controls: feed-forward because muscle coactivation is chosen and becomes effective before the initiation of the movement; feedback because the actual compensatory forces are determined by the instantaneous response to positional errors.

In similar situations, where the detailed time course of the disturbance cannot be predicted, a form of feedback control more sophisticated than segmental reflexes is in the repertoire of human control: event-driven intermittent control, based on a short-term prediction of relevant behavioral features such as the stability/instability of the ongoing action.

Classical (Psychometric) Test Theory

Rolf Steyer, Friedrich-Schiller-Universität, Jena, Germany

Abstract

Classical test theory (CTT) has been developed to quantify measurement error and to solve related problems such as correcting observed dependencies between variables (e.g., correlations) for attenuation due to measurement errors. Basic concepts of CTT are true score and measurement error variables. These concepts are defined as specific conditional expectations and their residuals, respectively. The definitions of these concepts already imply a number of properties that were considered axioms in early presentations of CTT. Models of CTT consist of assumptions about the true score and error variables allowing to identify the theoretical parameters (such as true score variance and error variance) from the variances and covariances of the observable measurements (test score variables). A number of implications of the assumptions defining models of CTT may be tested empirically via structural equation modeling. Hinting at more recent theories and their goals such as item response theory, generalizability theory, and latent state-trait theory concludes this article.

Introduction

One of the most striking and challenging phenomena in the social sciences is the unreliability of its measurements: measuring the same attribute twice often yields two different results. If the same measurement instrument is applied twice such a difference may sometimes be due to a change in the measured attribute itself. Sometimes these changes in the measured attribute are due to the mere fact of measuring. People learn when solving tasks, and they change their attitude when they reflect on statements in an attitude questionnaire, for instance. In other cases, the change of the measured attribute is due to developmental phenomena or to learning between occasions of measurement. However, if change of the attribute can be excluded, two different results in measuring the same attribute can be explained only by measurement error.

Classical (psychometric) test theory (CTT) aims at studying the reliability of a (real-valued) test score variable (measurement, test) that maps a crucial aspect of qualitative or quantitative observations into the set of real numbers. Aside from determining the reliability of a test score variable itself CTT allows answering questions such as

1. How do two random variables correlate once the measurement error is filtered out (correction for attenuation)?
2. How dependable is a measurement in characterizing an attribute of an individual unit, i.e., which is the confidence interval for the true score of that individual with respect to the measurement considered?
3. How reliable is an aggregated measurement consisting of the average (or sum) of several measurements of the same unit or object (Spearman–Brown formula for test length)?
4. How reliable is a difference, e.g., between a pretest and posttest?

Basic Concepts of Classical Test Theory

Primitives

In the framework of CTT, each measurement (test score) is considered being a value of a random variable Y consisting of two components: a true score and an error score. Two levels, or more precisely, two random experiments may be distinguished: (1) sampling an observational unit (e.g., a person) and (2) sampling a score within a given unit. Within a given unit, the true score is a parameter, i.e., a given but unknown number characterizing the attribute of the unit, whereas the error is a random variable with an unknown distribution. The true score of the unit is defined to be the expectation of this intra-individual distribution.

Taking the across units, perspective, i.e., joining the two random experiments, the true score is considered itself being a value of a random variable (the true score variable). The error variable is again a random variable, the distribution of which is a mixture of the individual units, error distributions. Most theorems of CTT (see, e.g., Lord and Novick, 1968) are formulated from this across units' perspective allowing to talk about the correlation of true scores with other variables, for instance.

More formally, CTT refers to a (joint) random experiment of (1) sampling an observational unit u (such as a person) from a set Ω_U of units (called the population) and (2) registering one or more observations out of a set Ω_O of possible observations. The set of possible outcomes of the random experiment is the set product: $\Omega = \Omega_U \times \Omega_O$. The elements of Ω_O, the observations, might be qualitative (such as "answering in category a of item 1 and in category b of item 2"), quantitative (such as reaction time and alcohol concentration in the blood), or consisting of both qualitative and quantitative components. In psychology, the measurements are often defined by test scoring rules prescribing how the observations are transformed into test scores. (Hence, these measurements are also often called tests or test score variables.) These scoring rules may just consist of summing initial scores of items (defining a psychological scale) or might be more sophisticated representations of observable responses of the units. CTT does not prescribe the definition of the test score variables. It just additively decomposes them into true score variables and error variables. Substantive theory and empirical validation studies are necessary in order to decide whether or not a given test score variable is meaningful. CTT only helps disentangling the variances of its true score and error components.

Table 1 Basic concepts of classical test theory

Primitives	
The set of possible outcomes of the random experiment	$\Omega = \Omega_U \times \Omega_O$
Test score variables	Y_i: $\Omega \rightarrow \mathrm{IR}$
Projection	U: $\Omega \rightarrow \Omega_U$
Definition of the theoretical variables	
True score variable	$\tau_i = E(Y_i \mid U)$
Measurement error variable	$\varepsilon_i = Y_i - \tau_i$

Referring to the joint random experiment described above the mapping U: $\Omega \rightarrow \Omega_U$, $U(\omega) = u$ (the unit or person projection) may be considered a qualitative random variable having a joint distribution with the test score variables Y_i. Most theorems of CTT deal with two or more test score variables (tests) Y_i and the relationship between their true score and error components. (The index i refers to one of several tests considered.)

The Core Concepts: True Score and Error Variables

Using the primitives introduced above, the true score variable $\tau_i = E(Y_i \mid U)$ is defined by the conditional expectation of the test Y_i given the variable U. The values of the true score variable τ_i are the conditional expected values $E(Y_i \mid U = u)$ of Y_i given the unit u. They are also called the true scores of the unit u with respect to Y_i. Hence, these true scores are the expected values of the intraindividual distributions of the Y_i. The measurement error variables ε_i are simply defined by the difference $\varepsilon_i = Y_i - \tau_i$. Table 1 summarizes the primitives and definitions of the basic concepts of CTT.

Properties of True Score and Error Variables

Once the true score variables and error variables are defined a number of properties (Table 2) can be derived, some of which are known as the axioms of CTT. At least since Novick's (1966) and Zimmerman's (1975, 1976) papers it is well known, however, that all these properties already follow from the definition of true score and error variables. They are not new and independent assumptions as has been originally proposed (see, e.g., Gulliksen, 1950). All equations in Table 2 are no assumptions. They are inherent properties of true scores and errors. Hence, trying to test or falsify these properties empirically would be meaningless just in the same way as it is meaningless to test whether or not a bachelor is really unmarried. The property of being unmarried is an inherent part or logical consequence of the concept of a bachelor.

Only one of the 'axioms of CTT' does not follow from the definition of true score and error variables: uncorrelatedness of error variables among each other. Hence, uncorrelatedness of errors has another epistemological status as the properties displayed in Table 2 (the other 'axioms'). Uncorrelatedness of errors is certainly a desirable and useful property; but it might be wrong in specific empirical applications (see, e.g., Zimmerman and Williams, 1977). It in fact is an assumption and it plays a crucial rule in defining models of CTT.

Equation [1] of Table 2 is a simple rearrangement of the definition of the error variable. Equation [2] shows that the variance of a test score variable, too, has two additive components: the variance of the true score variable and the variance of the error variable. This second property follows from Eqn [3] according to which a true score variable is uncorrelated with a measurement error variable, even if they pertain to different test score variables Y_i and Y_j. Equation [4] states that the expected value of an error variable is zero, whereas Eqn [5] implies that the expected value of an error variable is zero within each individual observational unit u. Finally, according to Eqn [6] the conditional expectation of an error variable is also zero for each mapping of U. This basically means that the expected value of an error variable is zero in each subpopulation of observational units.

Additional Concepts: Reliability, Unconditional, and Conditional Error Variances

Although the true score and error variables defined above are the core concepts of CTT, it is impossible, in general, to learn something about the true score and error scores themselves in empirical applications. What is possible, however, is to estimate the variances of the true score and error variables in a random sample (consisting of repeating many times the random experiment described earlier). The variance $\mathrm{Var}(\varepsilon_i)$ of the measurement error may be considered a gross parameter representing the degree of unreliability. A normed parameter of unreliability is $\mathrm{Var}(\varepsilon_i)/\mathrm{Var}(Y_i)$, the proportion of the variance of Y_i due to measurement error. Its counterpart is $1 - \mathrm{Var}(\varepsilon_i)/\mathrm{Var}(Y_i)$, i.e.,

$$\mathrm{Rel}(Y_i) = \mathrm{Var}(\tau_i)/\mathrm{Var}(Y_i) \qquad [7]$$

Table 2 Properties of true score and error variables implied by their definition

Decomposition of the variables	$Y_i = \tau_i + \varepsilon_i$	[1]
Decomposition of the variances	$\mathrm{Var}(Y_i) = \mathrm{Var}(\tau_i) + \mathrm{Var}(\varepsilon_i)$	[2]
Other properties of true score and error variables implied by their definition	$\mathrm{Cov}(\tau_i, \varepsilon_j) = 0$	[3]
	$E(\varepsilon_i) = 0$	[4]
	$E(\varepsilon_i \mid U) = 0$	[5]
for each (measurable) mapping of U:	$E[\varepsilon_i \mid f(U)] = 0$	[6]

the reliability of Y_i. This coefficient varies between zero and one. In fact, most theorems and most empirical research deal with this coefficient of reliability. The reliability coefficient conveniently informs about the dependability of the measurement in one single number.

In early papers on CTT, reliability of a test has been defined by its correlation with itself (see, e.g., Thurstone, 1931). However, this definition is only metaphoric, because a variable always correlates perfectly with itself. What is meant is to define reliability by the correlation of 'parallel tests' (see below). The assumptions defining parallel tests in fact imply that the correlation between two test score variables is the reliability. Note that the definition of reliability via Eqn [7] does not rest on any assumption other than $0 < \mathrm{Var}(Y_i) < \infty$.

Reliability is useful in comparing different instruments with each other if they are applied to the same population. Used in this way, reliability in fact helps in evaluating the quality of measurement instruments. It may not be useful, however, under all circumstances, to infer the dependability of measures of an individual unit. For the latter purpose, one might rather look at the conditional error variance $\mathrm{Var}(\varepsilon_i \mid U = u)$ given a specific observational unit u or at the conditional error variances $\mathrm{Var}(\varepsilon_i \mid \tau_i = t)$ given the subpopulation with true score $\tau_i = t$.

Models of Classical Test Theory

The definitions of true score and error variables have to be supplemented by assumptions defining a model if the theoretical parameters such as the reliability are to be computed by empirically estimable parameters such as the means, variances, covariances, or correlations of the test score variables. Table 3 displays the most important of these assumptions and the most important models defined by combining some of these assumptions.

The assumptions (a_1)–(a_3) specify in different ways the assumption that two tests Y_i and Y_j measure the same attribute. Such an assumption is crucial for inferring the degree of reliability from the discrepancy between two measurements of the same attribute of the same person. Perfect identity or 'τ-equivalence' of the two true score variables is assumed with (a_1). With (a_2) this assumption is relaxed: the two true score variables may differ by an additive constant. Two balances, for instance, will follow this assumption if at least one of them yields a weight that is always one pound larger than the weight indicated by the other balance, irrespective of the object to be weighed. According to assumption (a_3), the two tests measure the same attribute in the sense that their true score variables are linear functions of each other.

The other two assumptions deal with properties of the measurement errors. With (b) one assumes measurement errors pertaining to different test score variables to be uncorrelated. In (c) equal error variances are assumed, i.e., these tests are assumed to measure equally well.

Parallel Tests

Definition: The most simple and convenient set of assumptions is the model of parallel tests. Two tests Y_i and Y_j are defined to be parallel if they are τ-equivalent, their error variables are uncorrelated, and they have identical error variances. Note that assumption (a_1) implies that there is a uniquely defined latent variable being identical to each of the true score variables. Hence, one may drop the index i and denote this latent variable by η. The assumption of τ-equivalence may equivalently be written $Y_i = \eta + \varepsilon_i$, where $\varepsilon_i = Y_i - E(Y_i \mid U)$.

Identification: For parallel tests the theoretical parameters may be computed from the parameters characterizing the distribution of at least two test score variables, i.e., the theoretical parameters are identified in this model if $m \geq 2$. According to Table 4 the expected value of η is equal to the expected value of each of the tests, whereas the variance of η can be computed from the covariance of two different tests. The variance $\mathrm{Var}(\varepsilon_i)$ of the measurement error variables may be computed by the difference $\mathrm{Var}(Y_i) - \mathrm{Cov}(Y_i, Y_j)$, $i \neq j$. Finally, the reliability $\mathrm{Rel}(Y_i)$ is equal to the correlation $\mathrm{Corr}(Y_i, Y_j)$ of two different test score variables.

Testability: The model of parallel tests implies several consequences that may be tested empirically. First, all parallel tests Y_i have equal expectations $E(Y_i)$, equal variances $\mathrm{Var}(Y_i)$, and equal covariances $\mathrm{Cov}(Y_i, Y_j)$ in the total population. Second, parallel tests also have equal expectations in each subpopulation (Table 4).

Note that these hypotheses may be tested separately and/or simultaneously as a single multidimensional hypothesis in the framework of simultaneous equation models via AMOS (Arbuckle, 2006), EQS (Bentler, 2004), LISREL (Mels, 2006),

Table 3 Assumptions and some models of CTT

Assumptions used to define some models of CTT	
(a_1) τ-Equivalence	$\tau_i = \tau_j$
(a_2) Essential τ-equivalence	$\tau_i = \tau_j + \lambda_{ij}$, $\lambda_{ij} \in \mathrm{IR}$
(a_3) τ-Congenerity	$\tau_i = \lambda_{ij0} + \lambda_{ij1}\,\tau_j$, $\lambda_{ij0}, \lambda_{ij1} \in \mathrm{IR}$, $\lambda_{ij1} > 0$
(b) Uncorrelated errors	$\mathrm{Cov}(\varepsilon_i, \varepsilon_j) = 0$, $i \neq j$
(c) Equal error variances	$\mathrm{Var}(\varepsilon_i) = \mathrm{Var}(\varepsilon_j)$
Models defined by combining these assumptions	
Parallel tests are defined by assumptions (a_1), (b), and (c).	
Essentially τ-equivalent tests are defined by assumptions (a_2) and (b).	
Congeneric tests are defined by assumptions (a_3) and (b).	

The equations refer to each pair of tests Y_i and Y_j of a set of tests $Y_1, \ldots, Y_m$, their true score variables, and their error variables, respectively.

Table 4 The model of parallel tests

Definition	*Assumptions (a_1), (b), and (c) of Table 3*
Identification	$E(\eta) = E(Y_i)$
	$\mathrm{Var}(\eta) = \mathrm{Cov}(Y_i, Y_j)$, $i \neq j$
	$\mathrm{Var}(\varepsilon_i) = \mathrm{Var}(Y_i) - \mathrm{Cov}(Y_i, Y_j)$, $i \neq j$
	$\mathrm{Rel}(Y_i) = \mathrm{Corr}(Y_i, Y_j)$, $i \neq j$
Testability	
in the total population	$E(Y_i) = \mu$
	$\mathrm{Var}(Y_i) = \sigma^2_Y$
	$\mathrm{Cov}(Y_i, Y_j) = \sigma^2_\eta$
within each subpopulation s	$E^{(s)}(Y_i) = \mu_s$

The indices i and j refer to tests and the superscript s to a subpopulation. The equations are true for each test Y_i of a set of parallel tests $Y_1, \ldots, Y_m$ or for each pair of two such tests, their true score variables, and their error variables, respectively.

Mplus (Muthén and Muthén, 2007), and others. Such a simultaneous test may even include the hypotheses about the parameters in several subpopulations (Table 4). What is not implied by the assumptions of parallel tests is the equality of the variances and the covariances of the test score variables between different subpopulations.

For parallel tests $Y_1 + \ldots + Y_m$ as defined in Table 4, the reliability of the sum score $S = Y_1 + \ldots + Y_m$ may be computed by the Spearman–Brown formula for lengthened tests:

$$\mathrm{Rel}(S) = \mathrm{Rel}(S/m) = \frac{m \cdot \mathrm{Rel}(Y_1)}{1 + (m-1) \cdot \mathrm{Rel}(Y_1)}$$

Using this formula the reliability of an aggregated measurement consisting of the sum (or average) of m parallel measurements of the same unit can be computed. For $m = 2$ and $\mathrm{Rel}(Y) = 0.80$, for instance, the Spearman–Brown formula yields

$$\mathrm{Rel}(S) = 2 \cdot 0.80 / 1 + (2-1) \cdot 0.80 \approx 0.89$$

The Spearman–Brown formula may also be used to answer the opposite question. Suppose there is a test being the sum of m parallel tests and this test has reliability $\mathrm{Rel}(S)$. What would be the reliability $\mathrm{Rel}(Y_1)$ of the m parallel tests? For example, if $m = 2$, what would be the reliability of a test half if $\mathrm{Rel}(S) = 0.90$?

Essentially τ-Equivalent Tests

Definition: The model of essentially τ-equivalent tests is less restrictive than the model of parallel tests. Two tests Y_i and Y_j are defined to be essentially τ-equivalent if their true score variables differ only by an additive constant (assumption (a_2) in Table 3) and if their error variables are uncorrelated (assumption (b) in Table 3). Assumption (a_2) implies that there is a latent variable η that is a translation of each of the true score variables, i.e., $\eta = \tau_i + \lambda_i$, $\lambda_i \in \mathrm{IR}$, such that $Y_i = \eta + \lambda_i + \varepsilon_i$, where $\varepsilon_i = Y_i - E(Y_i \mid U)$ and $\lambda_i \in \mathrm{IR}$.

Also note that the latent variable η is uniquely defined up to a translation. Hence, it is necessary to fix the scale of the latent variable η. This can be done by fixing one of the coefficients λ_i (e.g., $\lambda_1 = 0$) or by fixing the expected value of η (e.g., $E(\eta) = 0$).

Table 5 summarizes the assumptions defining the model and the consequences for identification and testability. In this model, the reliability cannot be identified any more by the correlation between two tests. Instead the reliability is identified by $\mathrm{Rel}(Y_i) = \mathrm{Cov}(Y_i, Y_j)/\mathrm{Var}(Y_i)$, $i \neq j$. Furthermore, the expected values of different tests are not identical any more within each subpopulation. Instead, the differences between the expected values $E^{(s)}(Y_i) - E^{(s)}(Y_j)$ of two essentially τ-equivalent tests Y_i and Y_j are the same in each and every subpopulation. All other properties are the same as in the model of parallel tests. Again, all these hypotheses may be tested via structural equation modeling.

For essentially τ-equivalent tests $Y_1, \ldots, Y_m$, the reliability of the sum score $S = Y_1 + \ldots + Y_m$ may be computed by Cronbach's coefficient α:

$$\alpha = \frac{m}{m-1}\left(1 - \frac{\sum_{i=1}^{m} \mathrm{Var}(Y_i)}{\mathrm{Var}(S)}\right)$$

This coefficient is a lower bound for the reliability of S if only uncorrelated errors are assumed.

Table 5 The model of essentially τ-equivalent tests

Definition	*Assumptions (a_2) and (b) of Table 3*
Fixing the scale of η	$E(\eta) = 0$
Identification	$\mathrm{Var}(\eta) = \mathrm{Cov}(Y_i, Y_j)$, $i \neq j$
	$\mathrm{Var}(\varepsilon_i) = \mathrm{Var}(Y_i) - \mathrm{Cov}(Y_i, Y_j)$, $i \neq j$
	$\mathrm{Rel}(Y_i) = \mathrm{Cov}(Y_i, Y_j)/\mathrm{Var}(Y_i)$, $i \neq j$
Testability	
in the total population	$\mathrm{Cov}(Y_i, Y_j) = \sigma_\eta^2$
in each subpopulation s	$E^{(s)}(Y_i) - E^{(s)}(Y_j) = E^{(s)}(Y_i - Y_j) = \lambda_{ij}$

The indices i and j refer to tests and the superscript s to a subpopulation. The equations are true for each test Y_i of a set of tests $Y_1, \ldots, Y_m$ or for each pair of two such tests, their true score variables, and their error variables, respectively.

τ-Congeneric Tests

Definition: The model of τ-congeneric tests is defined by the assumptions (a_3) and (b) in Table 3. Hence, two tests Y_i and Y_j are called τ-congeneric if their true score variables are positive linear functions of each other and if their error variables are uncorrelated. Assumption (a_3) implies that there is a latent variable η such that each true score variable is a positive linear function of it, i.e., $\tau_i = \lambda_{i0} + \lambda_{i1}\eta$, λ_{i0}, $\lambda_{i1} \in \mathrm{IR}$, $\lambda_{i1} > 0$, or equivalently: $Y_i = \lambda_{i0} + \lambda_{i1}\eta + \varepsilon_i$, where $\varepsilon_i = Y_i - E(Y_i \mid U)$.

The latent variable η is uniquely defined up to positive linear functions. Hence, in this model, too, it is necessary to fix the scale of η. This can be done, e.g., by fixing a pair of the coefficients (e.g., $\lambda_{i0} = 0$ and $\lambda_{i1} = 1$) or by fixing the expected value and the variance of η (e.g., $E(\eta) = 0$ and $\mathrm{Var}(\eta) = 1$).

Table 6 summarizes the assumptions defining the model and the consequences for identification and testability assuming $E(\eta) = 0$ and $\mathrm{Var}(\eta) = 1$. Other ways of fixing the scale of η would imply different formula. As can be seen from the formulas in Table 6, the model of τ-congeneric variables and all its parameters are identified if there are at least three different tests for which assumptions (a_3) and (b) hold. The covariance structure in the total population implied by the model may be tested empirically if there are at least four test score variables. Only in this case the model has fewer theoretical parameters determining the covariance matrix of the test score variables than there are elements in this covariance matrix. The implications for the mean structure are testable already for three test score variables provided the means of the test score variables are available in at least four subpopulations.

Other Models of CTT

The models treated above are not the only ones that can be used to determine the theoretical parameters of CTT such as reliability, true score variance, and error variance. In fact, the models dealt with are limited to unidimensional models. True score variables, however, may also be decomposed into several latent variables. Confirmatory factor analysis provides a powerful methodology to construct, estimate, and test models with multidimensional decompositions of true score variables. Note, however, that not each factor model is based on CTT. For instance, there are one-factor models that are not models of τ-congeneric variables in terms of CTT. A model with

Table 6 The model of τ-congeneric tests

Definition	*Assumptions (a_3) and (b) of Table 3*
Fixing the scale of η	$E(\eta) = 0$ and $\mathrm{Var}(\eta) = 1$
Identification	$\lambda_{i1} = \sqrt{\dfrac{\mathrm{Cov}(Y_i, Y_j)\ \ \mathrm{Cov}(Y_i, Y_k)}{\mathrm{Cov}(Y_j, Y_k)}}, \quad i \neq j, \quad i \neq k, \quad j \neq k$
	$\mathrm{Var}(\varepsilon_i) = \mathrm{Var}(Y_i) - \lambda_{i1}^2$
	$\mathrm{Rel}(Y_i) = \lambda_{i1}^2 / \mathrm{Var}(Y_i)$
Testability in the total population	$\dfrac{\mathrm{Cov}(Y_i, Y_k)}{\mathrm{Cov}(Y_j, Y_k)} = \dfrac{\mathrm{Cov}(Y_i, Y_l)}{\mathrm{Cov}(Y_j, Y_l)}, \quad i \neq k, i \neq l, j \neq k, j \neq l$
between subpopulations	$\dfrac{E^{(1)}(Y_i) - E^{(2)}(Y_i)}{E^{(1)}(Y_j) - E^{(2)}(Y_j)} = \dfrac{E^{(3)}(Y_i) - E^{(4)}(Y_i)}{E^{(3)}(Y_j) - E^{(4)}(Y_j)}$

The indices i and j refer to tests and the superscripts to one of four subpopulations.

one common factor and several specific but uncorrelated factors is a counter example. The common factor is not necessarily a linear function of the true score variables, and the specific factors are not necessarily the measurement error variables as defined in CTT.

Some Practical Issues

Once a measurement or test score has been obtained for a specific individual, one might want to know how dependable that individual measurement is. If the reliability of the measurement is known and if one assumes a normal distribution of the measurement errors, which is homogeneous for all individuals, the 95% confidence interval for the true score of that individual with respect to the measurement Y_i can be computed by

$$Y_i \pm 1.96 \cdot \sqrt{\mathrm{Var}(Y_i) \cdot (1 - \mathrm{Rel}(Y_i))}$$

Another result deals with the correlation between two true score variables. If the reliabilities for two test score variables Y_1 and Y_2 are known, and assuming uncorrelated measurement errors, one may compute

$$\mathrm{Corr}(\tau_1, \tau_2) = \frac{\mathrm{Corr}(Y_1, Y_2)}{\sqrt{\mathrm{Rel}(Y_1)} \cdot \sqrt{\mathrm{Rel}(Y_2)}}$$

This equation is known as the correction for attenuation.

Another important issue deals with the reliability of a difference variable, for instance, a difference between a pretest Y_1 and a posttest Y_2. Assuming equal true score and error variances between pre- and posttest implies identical reliabilities, i.e., $\mathrm{Rel}(Y_1) = \mathrm{Rel}(Y_2) = \mathrm{Rel}(Y)$. If, in addition, uncorrelated measurement errors are assumed, the reliability $\mathrm{Rel}(Y_1 - Y_2) = \mathrm{Var}(E(Y_1 - Y_2) \mid U)/\mathrm{Var}(Y_1 - Y_2)$ of the difference $Y_1 - Y_2$ may be computed by

$$\mathrm{Rel}(Y_1 - Y_2) = \frac{\mathrm{Rel}(Y) - \mathrm{Corr}(Y_1, Y_2)}{1 - \mathrm{Corr}(Y_1, Y_2)}$$

According to this formula, the reliability of a difference between pre- and posttest is always smaller than the reliability of the pre- and posttest, provided the assumptions mentioned above hold. In the extreme case in which there is no differential change, i.e., $\tau_2 = \tau_1 + \text{constant}$, the reliability coefficient $\mathrm{Rel}(Y_1 - Y_2)$ will be zero. Of course, this does not mean that the change is not dependable. It only means that there is no variance in the change, since each individual changes in the same amount. This phenomenon has lead to much confusion about the use of measuring change (see, e.g., Cronbach and Furby, 1970; Harris, 1963; Rogosa, 1995). Most of these problems are now solved by structural equation modeling, allowing the inclusion of latent change variables such as in growth curve models (see, e.g., McArdle & Epstein, 1987; Willet & Sayer, 1996) or, more directly, in true change models (Steyer, Eid, & Schwenkmezger, 1997; Steyer, Partchev, & Shanahan, 2000). Models of this kind are not hampered any more by reliability problems and allow one to explain inter differences in intra change.

Discussion

It should be noted that CTT refers to the population level, i.e., to the random experiment of sampling a single observational unit and assessing some of its behavior (Table 1). CTT does not refer to sampling models that consist of repeating this random experiment many times. Hence, no questions of statistical estimation and hypothesis testing are dealt with. Of course, the population models of CTT have to be supplemented by sampling models when it comes to applying statistical analyses, e.g., via structural equation modeling.

Aside from this more technical aspect, what are the limitations of CTT? First, CTT and its models are not really adequate for modeling answers to individual items in a questionnaire. This purpose is more adequately met by models of item response theory (IRT), which specify how the probability of answering in a specific category of an item depends on the attribute to be measured, i.e., on the value of a latent variable.

A second limitation of CTT is the exclusive focus on measurement errors. Inspired by generalizability theory (Cronbach et al., 1972; Shavelson and Webb, 1991), Tack (1980) and Steyer et al. (1989) presented a generalization of CTT, called latent state-trait theory, which explicitly takes into account person-specific situation effects, introduces formal

definitions of states and traits, and presents models that allow one to disentangle person effects, situation and/or interaction effects and measurement error. More recent presentations are Steyer et al. (1992), Steyer et al. (1999), as well as Steyer et al. (2012). Eid (1995, 1996) extended this approach to the normal ogive model for analyses on the item level.

The parameters of CTT are often said to be 'population dependent', i.e., meaningful only with respect to a given population. This is true for the variance of the true score variable and the reliability coefficient. The reliability (coefficient) of an intelligence test is different in the population of students than in the general population. This is a simple consequence of the restriction of the (true score) variance of intelligence in the population of students. However, such a restriction exists neither for the true score estimates of individual persons nor for the item parameters λ_i of the model of essentially τ-equivalent tests, for instance. The population dependence critique has often been forwarded by proponents of IRT models. They contrast it with the 'population independence' of the person and the item parameters of IRT models. However, 'population independence' also holds for the person and the item parameters of the model of essentially τ-equivalent tests, for instance.

In applications of CTT it is often assumed that the error variances are the same for each individual, irrespective of the true score of that individual. This assumption may be wrong, indeed, in many applications. In IRT models no such assumption is made. However, it is possible to assume different error variances for different (categories of) persons in CTT models as well. In this case, the unconditional error variance and the reliability coefficient are not the best available information for inferring the dependability of individual true score estimates. In this case one should seek to obtain estimates of conditional measurement error variances for specific classes of persons. It is to be expected that persons with high true scores have a higher measurement error variance than those with medium true scores and that those with low true scores have a higher error variance again. (This would be due to floor and ceiling effects.) Other patterns of the error variance depending on the size of the true score may occur as well.

Such phenomena do not mean that true scores and error scores would be correlated; only the error variances would depend on the true scores. None of the properties listed in Table 2 would be violated. As mentioned before, the properties listed in Table 2 cannot be wrong in empirical applications. What could be wrong, however, is the true score interpretation of the latent variable in a concrete structural equation model. Misinterpretations of this sort can be prevented most effectively by empirical tests of the hypotheses listed in the testability sections of Tables 4–6.

The most challenging critique of many applications of CTT is that they are based on rather arbitrarily defined test score variables. If these test score variables are not well chosen, any model based on them is not well founded, too. Are there really good reasons to base models on sum scores across items in questionnaires? Why take the sum of the items as test score variables Y_i and not another way of aggregation such as a weighted sum, a product, or a sum of logarithms? Why aggregate and not look at the items themselves?

There is no doubt that IRT models are more informative than CTT models if samples are big enough to allow their application, if the items obey the laws defining the models, and if detailed information about the items (and even about the categories of polytomous items, such as in ratings scales) is sought. In most applications, the decision how to define the test score variables Y_i on which models of CTT are built is arbitrary, to some degree. It should be noted, however, that arbitrariness in the choice of the test score variables cannot be avoided all together. Even if models are based on the item level, such as in IRT models, one may ask, "Why these items and not other ones"? Whether or not a good choice has been made will be proved only in model tests and in validation studies. This is true for models of CTT as well as for models of alternative theories of psychometric tests.

Abstract

This article reviews the most commonly used tests for the assessment of speech and language processes in adults and children. We present reference models for speech and language evaluations as well as widely used procedures for the assessment of aphasia. The assessment of functional communication is also briefly presented. Finally, issues pertaining to assessing speech and language in special populations are discussed.

Introduction

The evaluation of speech and language is one of the most important tasks of speech–language pathologists and professionals from a variety of disciplines and backgrounds (neuropsychologists, physicians, nurses, etc.). The assessment session is often the first contact with clients and also constitutes the starting point of all clinical interventions. Because of the absence of biological markers or simple assessment methods, the early detection or diagnosis of speech and language problems remains dependent on various indirect assessments (i.e., speech or language functioning must be inferred from the client performance in various tasks devised to explore the different areas of this functioning) performed to identify specific impairments and eliminate other possible causes.

There are various purposes to conduct speech–language assessments. The main goal of screening is to determine whether a client has a problem or not. The output of this type of assessment is a 'pass' or 'fail' result, based on an established criterion that could lead to a more extensive or a follow-up assessment. Diagnosis and differential diagnosis assessments are usually performed to label the communication problem and/or to differentiate it from other disorders in which similar characteristics are usually reported.

Another important purpose to evaluation is to provide clinicians with a detailed description of the client's baseline level of functioning in all areas of communication in order to identify affected and preserved components, to plan for treatment, to establish treatment effectiveness, or to track progress over time through periodic reevaluations. These types of assessment require the clinician to consider all aspects of communication, including the different areas of speech (e.g., articulation, voice, resonance) and language (e.g., lexical access, comprehension, written spelling), but also important related abilities and components such as pragmatics, cognitive functions (e.g., attention, memory, visual perception), emotions, awareness of deficits, etc. The selection of evaluation tools is also conditioned by the specific objectives of assessments. Screening for a speech or language disorder is usually performed with standardized screening measures, whereas standardized norm-referenced tests are used for diagnosis and differential diagnosis assessments as well as for clinical treatment purposes (baseline, effectiveness, progress).

Reference Models for the Assessment of Speech and Language Impairment

The choice of a particular method of assessment, the selection of evaluation tools as well as the interpretation of results, is highly dependent not only on the clinician's own conception of speech and language functioning but also on the reference to a clinicopathological or cognitive model of assessment.

In the clinicopathological model, speech and language problems are considered as essential characteristics of clinical syndromes. These clinical syndromes are organized and classified according to neurological–neuropathological characteristics (e.g., deterioration of cortical tissue in a specific brain area) and according to semiology (e.g., sensitive and motor deficits, visuospatial deficits, language deficits, etc.). For the purpose of assessment, the emphasis is put on the precise identification of the diagnostic label that best corresponds to the observed deficits as well as to the identification of the possible etiology. For example, within this model, the general assessment process of an aphasic person essentially consists of (1) gathering case history data (e.g., cerebrovascular accident in the left frontal area), (2) administrating a specific test battery (e.g., the *Boston Diagnostic Aphasia Examination* (BDAE); Goodglass et al., 2000), (3) confronting the results and description of behavior (e.g., impaired fluency, impaired articulatory agility, relatively good auditory comprehension, agrammatism) with the classification of neurogenic acquired deficits of language, and (4) specifying the precise aphasic label (Broca's aphasia) that best fits these characteristics. If screening or labeling is the main goal of the assessment, the clinicopathological model is probably the best option. It is, however, certainly not so if the purpose of the evaluation is to localize the functional origin of deficits or to guide clinical practice. Knowing that a person presents with a Broca's aphasia may not be much help in identifying the specific components of language that are totally or partially affected or preserved. It also does not tell the clinician what intervention goals are appropriate, what treatment approaches will succeed best. Instead of resorting to a medical assessment model, clinicians may also use cognitive neuropsychological models, directly derived from information-processing theories, to evaluate language. In these models, cognitive functions, including language, are sustained by

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54048-3

specialized interconnected processing components, represented in functional architecture models. For example, as shown in Figure 1, the ability to orally produce a word in picture naming is conceived as a staged process in which the activation flow is initiated in a conceptual-semantic component and ends with the execution of articulation mechanisms.

An assessment process based on cognitive neuropsychological models consists in the localization of the impaired and preserved processing components for each language modality. This localization is performed through the administration of specific tasks or test batteries (e.g., *Psycholinguistic Assessments of Language Processing in Aphasia* (PALPA); Kay et al., 1992) aiming at the evaluation of each component and route of the model. For example, the evaluation of naming abilities in an aphasic person could be performed by the administration of tasks exploring the conceptual-semantic (e.g., semantic questionnaire), phonological output lexicon (e.g., picture-naming task controlled for frequency, familiarity, etc), and phonological output buffer (e.g., repetition of words and nonwords controlled for length) components. Important information regarding the level of impairments also arises from error analysis. With the same example, an anomic behavior could arise from distinct underlying deficits (e.g., in the activation of conceptual-semantic representations or in retrieving phonological forms of words in the output lexicon), leading to distinct types of errors (e.g., semantic substitutions, phonemic errors). The complete cognitive assessment process should allow the clinician to understand the client's deficits (i.e., surface manifestations, underlying origins, affected components) as well as to identify the strengths and weaknesses in his communication abilities. When recommended, the treatment may focus on the impaired levels of processing (i.e., function restoration) or on alternative processing routes (i.e., function reorganization) that will allow the client to communicate successfully.

Figure 1 Schematic depiction of the cognitive neuropsychological model of spoken picture naming.

Classical Tests for the Assessment of Aphasia

Aphasia is the most common disorder of communication resulting from brain damage (i.e., stroke, brain tumor, head trauma, infections). This affection mainly involves language problems of production and comprehension as well as disturbances in reading and spelling.

Bedside and Screening Tests

The patient's symptoms change rapidly during the first days and weeks following the brain damage. Moreover, patients are often too ill to complete an exhaustive aphasia examination and bedside or screening instruments may be useful to advise relatives and health care professionals about the global communication profile and the best means to communicate in functional situations. These instruments are also useful to help clinicians to determine the necessity of performing a more thorough and extensive assessment of language or to establish the priority of patients on a waiting list. In addition to actual screening tests (e.g., Aphasia Screening Test; Reitan, 1991; for an extensive list see Murray and Chapey, 2001; Spreen and Risser, 2003), clinicians also may administer shortened versions of comprehensive tests of aphasia (e.g., short form of the Token Test; Spellacy and Spreen, 1969; for an extensive list see Murray and Chapey, 2001). As pointed out by Spreen and Risser (2003), although bedside and screening tests may be used to identify language impairments in moderate and severe aphasics (language is obviously affected, even in simple and natural communication situations), they are inappropriate or of little use to distinguish the responses of individuals with mild deficits from those with normal language skills.

Comprehensive Examinations and Aphasia Batteries

As compared to bedside and screening tests, the main purpose of comprehensive examinations of aphasia is to provide an extensive description of language skills through the administration of tests designed to explore the different areas of language (i.e., spontaneous speech, naming, oral expression, auditory and written comprehension, repetition, reading, and writing). According to the reference model of assessment, the output of a comprehensive examination may consist in the identification of a particular diagnostic of aphasia with the description of severity of deficits in each language area (clinicopathological approach), or in the localization of specific impairments affecting functional processing components of language skills (cognitive neuropsychological approach).

There are several classical comprehensive examinations and aphasia batteries. The most widely used in clinical and research settings in English are BDAE (Goodglass et al., 2000), the *Western Aphasia Battery* (Kertesz, 1982), and the *Aphasia Diagnostic Profiles* (Helm-Estabrooks, 1992). All these standardized test batteries comprise different subtests (e.g., BDAE has 27 subtests) that assess all the dimensions of language in order to diagnose and classify aphasic syndromes according to clinical localization-based classifications (i.e., Broca's, Wernicke's aphasia, etc.). For a complete description and a critical review

of these instruments, and others not reported here, see Spreen and Strauss (1998), Murray and Chapey (2001), and Spreen and Risser (2003). PALPA (Kay et al., 1992) is a comprehensive test battery directly derived from the cognitive neuropsychology approach of assessment. This aphasia battery, commonly used in the United Kingdom, consists in a set of resource materials comprising 60 rigorously controlled tests that enable the user to select tasks "that can be tailored to the investigation of an individual patient's impaired and intact abilities." The scoring and analysis of errors give the clinician a detailed profile of language abilities, including reading and written spelling, which can be interpreted within current cognitive models of language. As compared to classical batteries of aphasia, the versatile and flexible nature of PALPA is, however, lessened by the lack of standardization and validity/reliability measures.

Tests for the Assessment of Specific Aspects of Language

Specific aspects of language behavior can also be assessed through the administration of several tests. These are often used to complete aphasia batteries but some of them also are used as screening tests. Clinicians may select these tests according to the different aspects of language they want to explore in depth, but also according to the underlying theoretical model of assessment. For example, comprehension may be tested through the administration of specific tests aiming at the discrimination of phonemic sounds (Phoneme Discrimination Test; Benton et al., 1994), semantics (*Pyramids and Palm Trees Test*; Howard and Patterson, 1992), sentence length and syntactic complexity (Auditory Comprehension Test for Sentences; Shewan, 1979), commands (Token Test; De Renzi and Vignolo, 1962), or narrative discourse (*Discourse Comprehension Test*; Brookshire and Nichols, 1993). Other tests are available for measuring verbal expression, spoken and written naming, verbal fluency, reading, writing, gestural abilities, etc. An extensive list of specific language function tests can be found in Spreen and Strauss (1998), Murray and Chapey (2001), and Spreen and Risser (2003).

The Assessment of Functional Communication

Traditional tests provide useful information on linguistic abilities and language impairments in aphasia. However, performance on these tests does not necessarily predict how a person will communicate in more naturalistic settings and everyday life. Instead of focusing on the importance and the nature of deficits, the functional communication approach of assessment aims at the impact of these deficits on the person's activities and participation in society. Functional communication skills may be assessed with specific structured tests or by rating scales and inventories of communication profiles. Structured tests such as *Communication Activities of Daily Living, Second Edition* (Holland et al., 1999) and the Amsterdam–Nijmegen Everyday Language Test (Blomert et al., 1994) have been devised to explore functional communication skills using role-play in daily life activities (shopping, dealing with a receptionist, etc.) and have shown themselves to be useful to track progress over time. However, while they are certainly more ecological than comprehensive examinations and tests for specific aspects of language, structured tests of functional communication do not necessarily give reliable views of the communication skills of a person in real-life situations. In this respect, rating scales and inventories of communication profiles are closer to functional situations. For example, the *Functional Assessment of Communication Skills for Adults* (Frattali et al., 1995) is a rating protocol of 43 items, on a seven-point scale, based on the observations made by the speech–language pathologist or other significant person in the following four domains: social communication (e.g., 'refers to familiar people by name'); communication of basic needs (e.g., 'makes needs to eat'); reading, writing, and number concepts (e.g., 'writes messages'); and daily planning (e.g., 'tells time'). For a more extensive description of these functional communication tools, and others not described here, see Murray and Chapey (2001) and Spreen and Risser (2003).

Classical Tests for the Assessment of Speech, Language, Reading, and Writing Impairment in Children

The assessment of language and communication in children can take place from infancy through adolescence, when cognitive abilities are developing. Therefore, the language assessment process must not only inform on current specific abilities, but has also to capture changes over time in the level, sequence, and rate of acquisition. The interrelationship between language and other cognitive and social skills is also of primary importance. As part of a larger process, usually performed by different professionals, the evaluation of language in children should be completed by an assessment of nonverbal communication, play and social skills, perception, attention and memory, behavior, etc. Moreover, because of the major influence it has on child development, the evaluation also has to consider the familial and social environment, especially with respect to adult–child interaction. The different components (e.g., sensitivity, promptness) as well as the context (e.g., physical settings, types of play, activities) in which this interaction takes place should be analyzed through specific assessment tools or through direct observation.

The assessment of preschool children (children aged 2–5 years) and school-age children (5–10 or 12 years) is usually based upon a combination of parent interviews, standardized tests, criterion-referenced instruments, developmental scales, and observations. All these tools and methods aim to explore both receptive and expressive language abilities in semantics, morphology, syntax, phonology, and pragmatics. Collecting a communication sample is also a frequently used method to analyze communication in terms of sentence length, intelligibility of speech, vocabulary, and conversational strengths and weaknesses. Similarly to tests for aphasia, preschool and school-age tests can be divided into two major categories: screening and diagnostic tests. The purpose of screening tests is to determine if the child's communication should be explored more extensively for the presence of a possible impairment. On the other hand, the main purposes of diagnostic tests

are to establish the presence or absence of a deficit in one or more areas of language, to identify a possible difference in language development, to determine the child's eligibility for clinical services, and to identify the targets for intervention. These instruments are devised to assess language development by reference to the parameters of the normal range.

Screening Tests

Screening tests are usually inexpensive and require minimal time for administration and interpretation of results. Many norm-referenced standardized instruments may be used to establish the child's general level of expressive and receptive language functioning as well as other areas of functioning. The following are a few examples of such screening tests. The *Denver Developmental Screening Test II* (Frankenburg et al., 1990), a standardized screening battery for children from birth to age 6, is designed to test the child's abilities in the following four domains: personal-social, fine motor, gross motor, and language (including expressive–receptive vocabulary). The *Transdisciplinary Play-Based Assessment, Second Edition* (Linder, 2008) is an informal assessment for children from birth to age 6. Through observation of the child's play with family members, peers, and professionals, children can be assessed in four critical developmental areas, namely sensorimotor, emotional and social, communication, and cognition. The *Bayley Scales of Infant and Toddler Development, Third Edition* (Bayley, 2005) is a screening test designed to assess children from 1 to 42 months in many aspects of their development, including language. The *Bracken Basic Concept Scale, Third Edition* (Bracken, 2006) is an assessment tool for language skills, cognitive development, and school readiness for children from 3 to 7 years comprising a receptive and expressive evaluation. Screening tests may also consist in large batteries exploring language and cognitive functions through tasks of general verbal and nonverbal intellectual abilities. For example, the *Wechsler Intelligence Scale for Children, Fourth Edition* (Wechsler, 2004) is the most widely used measure of verbal and nonverbal intelligence in individuals from age 6 years 0 months to 16 years 11 months. As a screening tool, this battery consists in 16 subtests of verbal comprehension, perceptual reasoning, working memory, and processing speed skills.

For school-age children, some large screening batteries specifically concern academic achievement. That is, for example, the case with the *Peabody Individual Achievement Test – Revised* (PIAT-R; Markwardt, 1998), which provides a screening measure of achievement in the areas of mathematics, reading recognition and comprehension, spelling, and general information. However, most of the tasks of these large screening batteries are multifactorial and are therefore not appropriate to assess specific language or cognitive processes. For this purpose, clinicians may select among various specific screening tests for preschool and school-aged children that focus only on language. Most of these instruments are designed to explore the different language components. That is the case, for example, with the *Fluharty Preschool Speech and Language Screening Test II* (Fluharty, 2001), which explores articulation, expressive and receptive vocabulary, and composite language in children from 2 to 6 years old. An exhaustive list of norm-referenced standardized screening tests of language can be found in Paul (2001).

Comprehensive Examinations and Batteries

As for screening, some diagnostic tools are designed to explore language skills as well as other aspects of development. That is the case, for example, with the *Communication and Symbolic Behavior Scales Developmental Profile* (Wetherby and Prizant, 1998), which includes tasks exploring expressive and receptive language, symbolic play, and nonverbal communication in children from 6 to 24 months old. Another example is the *Rossetti Infant–Toddler Language Scale* (Rossetti, 1990), which is used to assess attachment, play, gestures, and pragmatics, as well as language comprehension and expression in children from birth to 3 years old. There are also several standardized comprehensive batteries of language processing that comprise tests exploring exclusively some or all of the language areas. That is the case, for example, with the *Preschool Language Scale, Fourth Edition* (Zimmerman et al., 2002), which is used to identify specific strengths and weaknesses in receptive and expressive language skills in children from birth to 6 years 11 months. The *Test of Early Language Development, Third Edition* (Hresko et al., 1999) is a standardized tool used to assess receptive and expressive language development in children aged 2 through 8. The *Test of Language Development – Fourth Edition – Primary and Intermediate* (Hammill and Newcomer, 2008) is also a classic test for spoken language used to identify oral language proficiency in children aged 4 years 0 months to 17 years 11 months. The test comprises nine subtests (e.g., syntactic comprehension, word discrimination), which measure various aspects of oral language: vocabulary, semantics, syntax, morphology, phonology, and articulation. The *Clinical Evaluation of Language Fundamentals, Fourth Edition* (Semel et al., 2003) is a multidimensional battery that can be used in individuals between the ages of 5 and 21 years to explore semantics, expressive and receptive language, and syntax, as well as working memory. The *Comprehensive Assessment of Spoken Language* (Carrow-Woolfolk, 1999b), designed for children from age 3 to 21, is another comprehensive battery of language skills, comprising 15 tests that provide an assessment of expressive and receptive skills in four language categories: lexical/semantic, syntactic, supralinguistic, and pragmatics. An extensive list of available comprehensive examinations and batteries of language for children can be found in McCauley (2001), Paul (2001), Mattis and Luck (2002), and Haynes and Pindzola (2003).

Tests for Specific Aspects of Language

Different components of language can be affected with more or less intensity in children according to the origin of developmental disorders. Therefore, the in-depth assessment of language and communication disorders in children is a critical component in the clinical process. Core tests can be used to evaluate each of the language areas in order to identify specific impairments, establish baselines, and identify precise therapeutic and intervention goals. For example, there are several core tests and instruments for the evaluation of word retrieval (e.g., naming and verbal fluency tests), phonology (e.g., word and nonword repetition tests), receptive and expressive vocabulary (e.g., word definition tests), receptive and expressive

syntax and morphology (e.g., sentence-to-picture matching tests), and pragmatic skills (e.g., narrative production, story comprehension tests).

A combination of different tests, each focusing on specific language components, may also be used to establish such a language and communication profile. To assess articulation, clinicians may select the following standardized norm-referenced specific tests: the *Goldman–Fristoe Test of Articulation 2* (Goldman and Fristoe, 2000) for children from 2 years 0 months through 21 years 11 months, the *Structured Photographic Articulation Test II* (Dawson and Tattersall, 2001) for children from 3 to 9 years old, or the *Verbal Motor Production Assessment for Children* (Hayden, and Square, 1999), which assess the integrity of the motor speech system for children 3 through 12 years. There exist various tests to assess phonology in children. One can mention, for example, the *Phonological Awareness Test 2* (Robertson and Salter, 2007) for children from 5 to 9 years old, which assesses all the pre-reading skills, like explicit phonological knowledge, that are early indicators of reading success; the *Test of Auditory Processing Skills, Third Edition* (Martin and Brownell, 2005) for children from 4 to 18 years old; or the *Hodson Assessment of Phonological Patterns, Third Edition* (Hodson, 2004) for children 2 through 8 years old. With respect to vocabulary, clinicians may select the following standardized norm-referenced tests: the *Expressive One-Word Picture Vocabulary Test Revised* (Gardner, 2000), designed to explore expressive vocabulary in children from 2 to 18 years 11 months; the *Peabody Picture Vocabulary Test* (Dunn and Dunn, 1997), an assessment tool to explore receptive vocabulary in individuals from age 2 years 6 months to adulthood; the *Montgomery Assessment of Vocabulary Acquisition* (Montgomery, 2008), a test for expressive and receptive vocabulary in children from 3 to 12 years 11 months; the *Expressive Vocabulary Test, Second Edition* (Williams, 2007), a measure of expressive vocabulary and word retrieval for children from 2.5 years old to adulthood. Syntactic abilities can be assessed with the *Structured Photographic Expressive Language Test 3* (Dawson et al., 2003), which examines expressive use of morphology and syntax in children from 4 through 9 years 11 months, or with the *Test for Auditory Comprehension of Language, Third Edition* (Carrow-Woolfolk, 1999a), which is an individually administered measure of receptive spoken grammar and syntax for children from 3 to 9 years 11 months. Finally, the *Test of Narrative Language* (Gillam and Pearson, 2004) and the *Edmonton Narrative Norms Instrument* (Schneider et al., 2005) can be used to assess narrative discourse abilities in children from 5 to 11 years 11 months and children from 4 to 9 years old, respectively. A more complete description of available diagnostic tests adapted to preschool and school-age children can be found in McCauley (2001), Paul (2001), Mattis and Luck (2002), and Haynes and Pindzola (2003).

The Assessment of Reading and Writing

The relationship between language acquisition and academic achievement is well established. Developmental disorders of language in preschool children are frequently associated with later difficulties in learning to read and write. The most common referral for a speech–language pathology assessment concerns school-age children who encounter problems in progressing beyond the developing language phase and present with difficulties in learning and acquiring communicative and academic skills. As for other populations, but especially at this stage of development, a significant difficulty in assessing school-age children arises because of important comorbidity between language and learning disorders and other cognitive and clinical pathological profiles, such as attention deficit/hyperactivity or executive function disorders. Therefore, the assessment process should include specific tests of language and communication but also instruments designed for exploring other cognitive functions, such as attention, working memory, and executive functions. In addition to formal tests, another important source of information also comes from structured interviews of the child himself, his parents, and his teacher. With respect to language, phonological processing deficits are considered as an underlying cause of dyslexia and also play a role in developmental disorders of spelling. For example, dyslexic children often show problems with word and nonword repetition tasks, phonological awareness tasks (e.g., word and nonword segmentation tasks, phoneme manipulation, etc.), and working memory tasks for verbal material (i.e., word or digit span tasks). The semantic processing is another cognitive area highly related to reading and writing. School-age children usually learn new words through reading and writing. Those who encounter problems in reading and writing often present with poor vocabulary as well as with difficulty in word association and comprehension. Therefore, the assessment procedure for written language problems should be part of a more exhaustive evaluation of language and cognition. It should also include a close control of psycholinguistic parameters (e.g., orthographic regularity, lexical frequency) that are known to play an important role in written and spoken word recognition, reading comprehension, phoneme–grapheme conversion, decoding, etc. In addition to experimental tasks, one can resort to standardized achievement or specific tests of reading and writing skills. Among the most used of these achievement tests are *PIAT-R* (Markwardt, 1998), which comprises subtests of reading comprehension, reading recognition, and spelling, and the *Wide Range Achievement Test* (Wilkinson, 1993), a brief test measuring reading recognition, spelling, and arithmetic computation. Finally, to specifically assess reading and/or writing in children, clinicians may select the *Test of Early Written Language, Third Edition* (Hresko et al., 2012) for children 4 to 10 years 11 months, or the *Oral and Written Language Scales, Second Edition* (Carrow-Woolfolk, 2011) for children from 5 to 21 years 11 months, which assess reading comprehension and written expression. For a description of specific clinical tests of reading and writing, see Spreen and Strauss (1998) and Bailet (2001).

Classical Tests for the Assessment of Speech and Language Impairment in Special Populations

Referral for speech–language assessment not only concerns aphasia and developmental deficits of language but also involves individuals of different age groups presenting with various language and communication problems. In children

and adolescents, these references include language deficits in pervasive developmental disorders (e.g., autism, Asperger's disorder), mental retardation, attention deficit/hyperactivity disorder, specific language impairment, sensory deficits (hearing loss, blindness), acquired disorders (e.g., traumatic brain injury), stuttering, etc. In adults, referral for a speed–language evaluation may be required for language and communication deficits following right hemisphere damage, traumatic brain injury, Alzheimer's disease and other forms of dementia (e.g., primary progressive aphasia, semantic dementia), stuttering and other fluency problems, etc.

In children, adolescents, and adults, clinical assessments may also concern such speech problems as dysarthria, following a stroke and neurodegenerative illnesses or accompanying cerebral palsy, acquired or developmental apraxia of speech, etc. In addition to the conventional evaluation of basic language (or speech) skills, the assessment procedure in all these special populations involves specific aspects and particularities of speech and language. For example, because of the absence of biological markers or simple diagnosis methods, the early detection of dementia often depends on various assessment tools, including language and cognitive tests performed to exclude other possible disease processes or identify specific forms of a given disease. In that particular domain, the assessment of speech and language usually includes tests allowing for differential diagnosis. For example, tests that specifically tap either semantic processing or written spelling can contribute to differentiating common disease processes in the elderly population. Semantic deficits are prominent characteristics of individuals diagnosed with Alzheimer's disease and these individuals usually differ from patients diagnosed with vascular dementia or with the semantic variant of primary progressive aphasia because of the presence of surface dysgraphia, a specific spelling disorder.

It is obviously not possible to exhaustively describe here the various tests adapted to special populations. The reader will find a more complete description of such tests in McCauley (2001), Paul (2001), Haynes and Pindzola (2003), and Spreen and Risser (2003).

Conclusion

Language production and comprehension are complex cognitive skills that should not be considered in isolation in assessment procedures. The interrelation between language and other cognitive functions has to be captured, particularly with respect to the possible influence of attention, working memory, and executive functions on linguistic abilities. If possible, clinicians should always select valid and reliable norm-referenced tests to assess language and communication. Resorting to theoretical models of language functioning also appears of primary importance and may sometimes condition the utilization of experimental, well-controlled, assessment tasks. A comprehensive assessment of language and communication is more than just an evaluation of specific skills in terms of preservation or impairment of processing components and surface structures. The scope of assessment should be widened in order to provide information about physical, social, and emotional contexts of communication, cultural differences, and economic factors. The combination of these data, obtained through assessment tools and direct observations, should then allow the clinician to establish a complete portrait of functional communication abilities.

Classifications in Popular Music

Alex van Venrooij, University of Amsterdam, Amsterdam, The Netherlands
Vaughn Schmutz, UNC Charlotte, Charlotte, NC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The categorical system of popular music, such as genre categories, is a highly differentiated and dynamic classification system. In this article we present work that studies different aspects of these categorical systems in popular music. Following the work of Paul DiMaggio, we focus on four questions: How does the position of popular music vary in terms of its place in the cultural hierarchy and the manner in which it is legitimated? How do social and symbolic boundaries mutually shape each other? What are the consequences of boundary crossing in popular music, and do these effects vary across different subfields of popular music? How do classification systems in popular music change over time?

Introduction

From a sociological perspective, musical categories are based on cultural conceptions about types of music that are similar to or dissimilar from one another. Rather than being based on formal musical properties or sonic qualities alone, such conceptions of similarity or dissimilarity are influenced by a range of factors, including social relations, artistic conventions, characteristics of producers and audiences, broad systems of classification, and even production technologies. By describing musical categories as cultural, we highlight the shared meanings that enable a common system for classifying and evaluating music. Although they can become so taken for granted that they appear natural and inevitable, musical categories are constructed and upheld by social practices and cultural assumptions (Roy and Dowd, 2010). Yet while the boundaries between musical categories are symbolic in character, they create consequential distinctions between genres as well as between legitimate and illegitimate musical forms and musicians.

Perhaps the most familiar type of musical category is a genre, which Paul DiMaggio (1987: p. 441) defines as a set of 'artworks classified together on the basis of perceived similarities.' Relative to other cultural fields, popular music is characterized by a large and growing number of genres that vary considerably in terms of how much popularity they achieve and how long they endure (Lena, 2012). Indeed, some features of classification systems change and others persist as genres emerge, transform, and disappear. Despite the seemingly idiosyncratic characteristics of this process, genres often follow similar trajectories (Lena, 2012) and their boundaries both reflect and reinforce broader patterns of social relations (Roy, 2004; Roy and Dowd, 2010).

The symbolic boundaries that differentiate music genres are not the only categorical distinctions of interest to sociologists. Symbolic divisions also separate music that is legitimate from music that is illegitimate, music that is authentic from music that is inauthentic, music that is newsworthy from music that is unworthy of media attention, music that wins prestigious awards from music that is undeserving of such esteem, and so on. Such divisions may transcend generic boundaries, but reinforce boundaries based on artistic conventions or associated with social characteristics like race or gender. Musical classification systems vary not only in terms of how many genres they include, but also in the degree to which their categories are strongly bounded or hierarchically ranked (DiMaggio, 1987; van Venrooij, 2009). Indeed, the cultural standing of popular music itself and of particular popular genres can vary greatly across time and space.

Classification Systems

The work of DiMaggio (1987) has provided the theoretical foundation for much research on classification systems. His concept of artistic classification systems offers a number of insights. First, the study of classification systems needs to take into account both the consumption and production of art. According to DiMaggio (1987: p. 441), artistic classification systems consist of "the way that the work of artists is divided up both in the heads and habits of consumers *and* by the institutions that bound the production and distribution of separate genres" [italics in original]. On the one hand, classification systems arise out of processes of social distinction, whereby consumers use cultural objects to mark social boundaries. These 'ritual classifications' can thus be influenced by social structural factors at the societal level – such as stratification systems, elite cohesion, social and geographic mobility, etc. – that generate demand for cultural boundaries. On the other hand, classification systems are also influenced and mediated by 'classification processes' at the production side. DiMaggio (1987) identifies *commercial* classifications (the classifications used by commercial producers to market their products), *administrative* classifications (created and enforced by the state), and *professional* classifications (classifications driven by the incentives of artists to differentiate and mark boundaries). The study of classification systems thus needs to be attentive to the extent to which the categorical demands of consumers and the categories used by producers overlap, diverge, or mutually reinforce each other.

Second, DiMaggio also argues that classification systems have both a cognitive/symbolic as well as organizational/material dimension. This analytical distinction allows for analyzing processes of institutionalization whereby symbolic

categories can become 'objectified' in organizational practices, network structures of artists, or unequal resource distributions. If the symbolic and material boundaries of categories strongly overlap, chances are these categories become seen as taken for granted and 'natural.'

Third, the concept of classification *systems* implies the study of collections of categories, not of isolated genres or categories. It thus focuses on the relationship between categories – since categories are always defined vis-a-vis other categories. A single category is a logical impossibility, similar to clapping with one hand (see Mohr and White, 2008).

Fourth, artistic classification systems therefore are also studied in their formal characteristics. DiMaggio distinguishes four such formal characteristics. For one, artistic classification systems can vary in their *differentiation*, or the degree to which genres are institutionally bounded. Fields that are highly segmented with many identifiable genres are highly differentiated. Second, artistic classification systems can vary in the degree to which genres are ranked by prestige, which is an indicator of *hierarchy*. In more hierarchical systems, genres diverge widely in prestige and command unequal resources. A third dimension of variation is *universality*, or the degree to which there is agreement among members of a society in the ways they recognize and classify genres. Finally, artistic classification systems can vary in their *boundary strength*, or the degree to which genre boundaries are highly ritualized and difficult to transgress.

Although DiMaggio has mostly developed this theory for the analysis of the construction of the 'high culture' category in the United States, it has also proven relevant for understanding the categorical position and categorical systems of other fields (e.g., Baumann, 2007 on film; Verboord and van Rees, 2008 on literature; Zhao, 2005, 2008 on wine), including popular music. Below we will first discuss our research that builds on DiMaggio's work in comparing the legitimation of popular music in cross-national comparative perspective (cf Janssen et al., 2011). His work not only suggests reasons why the hierarchical classification system has been challenged in recent decades, but also why this process might vary between nations, and how this affects the trajectory of popular music. Second, we focus on research that investigates the homology between aesthetic and social boundaries, which develops out of the confluence of ritual and other types of classifications. Third, we investigate the dimension of boundary strength and whether there are penalties associated with crossing genre boundaries in popular music. Finally, we discuss research that looks at how classification systems in popular music develop over time, and how this work can be extended to analyze how new categories within popular music develop.

The Legitimacy of Popular Music in Comparative Perspective

Paul DiMaggio's (1987) influential theory of artistic classification systems has proven useful in analyzing cross-national comparative differences in the rise of popular music in the cultural hierarchy. His theory proposes a number of social structural factors and institutional mechanisms that might influence the differentiation, hierarchy, universality, and boundary strength of ritual classification systems. He has also described how the 'high culture system' in the United States gave way to a more differentiated, less hierarchical, less universal, and more weakly bounded classification system. His theory, however, also suggests that this process of 'declassification' might vary across nations, and thus for the position of popular music within the classification system.

Comparative research by Susanne Janssen et al. (2011) shows, indeed, that the legitimacy of popular music as a cultural category varied greatly over time and across countries. Such research supports the idea that social structural characteristics are associated with variation in classification systems and, therefore, with the relative position of popular music. Our own related research shows that these cross-national differences in classification systems also influence *how* a previously suspect cultural form, like popular music, is increasingly legitimated. Building on the work of Motti Regev (1994) and Shyon Baumann (2007) who focus on the legitimating ideology that promoted the aesthetic mobility of rock music and film, we investigated the evaluative criteria used to assess popular music releases in three countries; however, we criticized the idea that the rise of popular music in the cultural hierarchy could only be legitimated by assessing the worth of this cultural form as a 'serious art form' or, in other words, by the use of autonomous criteria of art (van Venrooij and Schmutz, 2010). This idea of artistic legitimation, we argued, takes for granted that the process of declassification in itself challenges the dominance and acceptance of 'art' as the single legitimate category. The differentiation of the music field and the corresponding flattening of its hierarchy could also result in the 'autonomization' of popular music and its aesthetic, thus making it less likely that popular music needs to be legitimated as art, but could also be legitimated by a 'popular aesthetic.'

In our comparison of popular music reviews in the United States, Germany, and the Netherlands, we find that differences in the boundary strength, hierarchy, and universality of their respective classification systems – based on differences in the educational and stratification systems in each country as well as their historic national repertoires – indeed lead to variation in ways of legitimating popular music. In Germany, which has a more hierarchical, universal, and ritually bounded classification system, music reviewers draw more exclusively on high art criteria to legitimate popular music albums. By contrast, the United States is characterized by a less hierarchical, universal, and ritually bounded classification system; as expected, American critics are much more likely to mix high art and popular aesthetic criteria in their reviews. Finally, Dutch reviewers are more likely to employ exclusively popular aesthetic criteria in their discourse about popular music albums. So although popular music gained much in attention from established critical institutions in all three countries, the differences in how they evaluated popular music were striking. In general, comparative research of this kind thus clearly shows that popular music itself is a cultural category and that its meanings vary over time and from one place to another.

Social and Symbolic Boundaries

The symbolic boundaries that distinguish one musical category from another are shaped by the social boundaries that divide

groups of people from one another. However, as argued by DiMaggio, the homology between aesthetic and social boundaries can be mediated and influenced by the commercial classifications used by for-profit firms. Genre classifications in the United States, for example, have historically varied in how tightly coupled they are with social boundaries based on race, class, or gender. In the early American recording industry, the dominant categorical system was largely focused on a class-based distinction between classical and popular music, yet Bill Roy (2004) demonstrates how musical categories also became overtly racialized and thereby more closely linked to social categories. 'Race records' and 'hillbilly music' were constructed musical categories by which the major recording firms explicitly linked musical styles to social categories based on race and class. The separation of the two categories had little to do with musical differences – rather, it was a business decision introduced by the Okeh Recording Company in its 1921 catalog – but other recording firms quickly adopted it and the categories soon became institutionalized. Thus, symbolic boundaries (i.e., music genres) and social boundaries (i.e., race) became tightly coupled in the field of American popular music with long-term consequences.

Although musical categories have become less overtly racialized over time, the *de facto* segregation of the musicians' union and of radio airplay continued to hinder the success of African American performers in the mainstream US music market (Dowd and Blyler, 2002). Furthermore, Keith Negus (1999) argues that this homology between racial and musical categories has implications for the cultural and organizational divisions of contemporary recording firms. In addition to being isolated from the resource-rich and decision-making centers of the major labels, genres like rap or salsa are also constrained by the cultural assumptions about their performers and their audiences. With regards to rap, major labels produce a 'discourse of the street' that constrains the range of musicians they embrace through a narrow cultural conception of authentic rap production, distribution, and performance. Similarly, the genre culture of salsa remains distant from the dominant interests of the major labels and is contained in distinct Latin music divisions that correspond to broader social divisions based on commodified Latin identities (Negus, 1999). In short, cultural assumptions about racial and ethnic groups are linked with musical categories in the contemporary recording industry.

Likewise, symbolic boundaries linked to gender have shaped the opportunities available to men and women in the popular music industry. Typically, the connection between gender and genre has constrained the prospects for women in popular music (Roy and Dowd, 2010). For instance, scholars across disciplines have called attention to the ways in which the masculinization of many popular music genres has limited the inclusion of women in jazz ensembles, rock and heavy metal bands, rap performance, and so on. While some opportunities have opened for women in popular music, cultural assumptions about gender frequently shape the roles and styles that are available to female musicians. For example, alternative rock bands in the 1990s were more open to women than their rock music predecessors, evidenced by a notable increase in female bass players during this period. Yet despite this slight decoupling between masculinity and rock music, Mary Ann Clawson (1999) found that the feminization of bass playing limited women to a more peripheral role as men gravitated toward higher status positions like lead singer or guitarist. Beyond alternative rock, Patti Donze (2011) has demonstrated that women represent a narrower range of artistic types relative to men in the mainstream music field. She uses latent class analysis of the labels attributed to male and female musicians to show how gendered and sexualized schemas relate to categorical distinctions in popular music.

The interplay between gender and symbolic boundaries can also be seen in research on cultural legitimacy and consecration in popular music. First, consider newspaper coverage of popular musicians in the United States, France, Germany, and the Netherlands from 1955 to 2005 (Schmutz, 2009). As genres gained greater legitimacy in the popular music hierarchy, measured by the amount of attention received in elite newspapers, their media coverage became increasingly male dominated. In other words, the more legitimate a genre became, the more its media coverage focused on male musicians and this pattern was consistent regardless of country or the genre that was gaining greater attention. Beyond the sheer quantity of media attention, cultural frameworks about art and gender influence the ways that music critics write about male and female musicians (Schmutz and Faupel, 2010). Not only are female musicians less likely to have their albums consecrated among the 'greatest of all time,' but also the few who do achieve such status are legitimated in subtly different ways. Whereas men are more likely to be described as autonomous, historically important, and with 'high art' terms, women are more likely to be legitimated through their emotional authenticity and their ties to others (Schmutz and Faupel, 2010).

The Consequences of Categories

The sociology of art considers the creation of artistic works as a collective and social enterprise (Becker, 1982). To account for the collective nature of the production, distribution, and reception of art, sociologists often point to the taken for granted and shared understandings that constrain and enable this collective production of art (cf Roy and Dowd, 2010). Especially relevant for the collective production of art are the shared understandings of categorical systems such as genres. Genres can be seen as consisting of rules and conventions shared by participants in particular genre worlds about ways of playing an instrument (the 'swing' of jazz drummers), the use of the voice (the 'rawness' of rock singers), the inclusion of instruments (the 'banjo' in bluegrass), or forms of presentation (the 'long hair' of heavy metal bands) or who can be legitimately part of the genre world (whether or not 'white' rappers are 'real,' etc. – see below). Genre categories can function as shorthand for a collection of conventions and enable the interaction between musicians – as when asked to play the rhythm 'more funky,' or put on a 'rock voice.' Genre categories are therefore frequently invoked in decision-making processes in the production and distribution of art (Negus, 1999), the evaluation and assessment of worth by critics (Schmutz, 2009; van Venrooij, 2009) as well as by consumers to organize their taste patterns (Bourdieu, 1984).

Confusion about the characteristics of a genre can impede its development. For instance, Christophe Boone et al. (2012) show how attempts to institutionalize modernistic music in Brussels was hampered by the fragmentation of the cultural elites and their ideas about which example should be followed: Francophone, Germanic, or hybrid form of modernistic music. The importance of consensus building on the key characteristics could also play a role in the mobilization and legitimation of popular musical forms. Genres that are 'hybrids' might be less easily institutionalized than genres that only marginally differ from already established genres. Such mutual understandings and expectations also tend to restrain the opportunities of producers to deviate from 'categorical imperatives' without sanction. Although musicians often do not want to be confined by genre categories, the collaborative nature of music production implies that musicians are bounded by the expectations others have of their genre identity. Musicians who, for example, depart from genre expectations can expect negative reactions from other participants in the art world, such as audiences, critics, or industry personnel. The history of popular music provides many anecdotal examples of this mechanism. Well-known cases include the criticism Bob Dylan received for deviating from the folk genre by introducing electronic instruments at the Newport Folk Festival or Neil Young being sued by his record label Geffen in 1983 for making genre-deviating albums that they considered musically uncharacteristic of Young's previous recordings.

A burgeoning literature on 'multiple category membership' indeed shows the negative consequences of transgressing categorical boundaries (for a review, see Hannan, 2010). Products and producers who do not have a 'crisp' identity but combine or cross categorical boundaries are found to be penalized in terms of several indicators of success, such as market appeal and critical ratings (Hsu, 2006). The main argument is that audiences are confused by 'fuzzy' identities, and react negatively or ignore products or producers they cannot make sense of with the schematic understandings of their existing classification systems.

These studies, however, tend to assume and study the effects of fuzziness in fields and markets that have established, stable, well-institutionalized classification systems. When classification systems are emergent, weak or in flux, and have not yet crystallized in well-developed categorical schemas, fuzziness might not lead to the same negative penalties as in mature, institutionalized classification systems. When classification systems are weakly bounded, the penalties for products that do not have a clear categorical fit tend to be lower. In other words, the work of DiMaggio (1987) provides reasons to assume that the penalties for 'boundary crossing' might be contingent on the boundary strength of the classification systems.

To investigate this possibility, we compared the constraining effects of genres within two subfields of popular music that are likely to have varying boundary strength of their classification systems (van Venrooij and Schmutz, 2012). We argue that classification systems in fields of large-scale production – the mainstream market – are more strongly institutionalized and therefore fuzziness tends to detract from being successful in that subfield. In fields of restricted production, the 'independent market,' however, the classification system – we argue – is weaker and more ambiguous, and thus fuzziness tends to not be penalized, and even valorized within this subfield.

We give several reasons why this difference between subfields might occur. The *first* reason concerns the entry barriers and competitive pressures in both subfields. DiMaggio (1987: p. 451) suggests that classification systems will be strongly differentiated, but weakly institutionalized in fields with lower entry barriers. If more participants enter the field than the field can absorb, the incentive among artists increases to 'make one's name' by attaching themselves to a new genre and thereby create more finely grained classification systems. In low entry fields, the classification system can therefore become highly differentiated but poorly institutionalized and only weakly bounded. Even though these differentiated categories might make sense to insiders and the ones who proposed them, the more specific the categories become, the less broadly accepted are the boundaries between them. As one of DiMaggio's (1987: p. 448) propositions reads, 'the more differentiated the system of classification, the less universal.' In the 'independent' subfield, the entry barriers are arguably lower than in the 'major' subfield. The 'indie labels' are, for example, more closely connected to the different music scenes and generally provide more opportunities for new artists than the major labels who invest more in their 'stars.'

The *second* reason follows from differences in the structure of organizations that produce and distribute the cultural products of artists in the restricted and large-scale fields. The 'autonomous' subfield consists of small entrepreneurial organizations that follow a 'professional logic' and delegate more discretion to artists or brokers, grant them more autonomy, and assign lesser influence to managers. This balance between artists and managers is important since they often have conflicting interests. Artists have a professional incentive to innovate, challenge existing tastes, and generate new cultural forms. Managers, however, are mostly concerned with routinely sorting the unfamiliar into the familiar to assure survival of the product within the 'decision chain' of the organization or tailor the sound of new bands in the mold of accepted genres in order to secure acceptance of the music 'downstream' by radio and retailers. The 'professional logic' of small entrepreneurial organizations places more weight on the importance of the former, and the greater autonomy of the artists can therefore strengthen the possibility that artists create music that does not fit with established categories or assign their own classifications onto their work, and thereby push toward greater differentiation of the genre classification system. The 'commercial logic' of larger bureaucratic culture-producing organizations grants less artistic autonomy to artists, gives more power to managers and marketers who are therefore more likely to uphold established genre categories. Moreover, the practice of 'portfolio management' at major labels assigns genres to different divisions within the company, which are monitored and controlled as separate units – a practice which also works against 'genre crossing' (Negus, 1999).

The *third* reason lies with the intended audiences of both subfields. The heteronomous field orients itself mainly toward success among mainstream audiences and the 'modal' consumer, whereas the autonomous field focuses on symbolic success among other producers, 'insider audiences,' aficionados, and critics. The insider audiences of the autonomous

field are equipped with the necessary 'code to decode' to understand and value the cultural products from the viewpoint of the field, and are therefore less likely to be confused by aesthetic innovation and experimentation than mainstream audiences. Rather than penalizing artists for crossing categorical boundaries, insider audiences are therefore more likely to value their quest for distinction and innovativeness.

Our study found that combining or hybridizing genre categories indeed leads to more severe penalization for albums in the mainstream subfield than in the independent subfield. Negative reactions by audiences and critics occur especially for musicians produced by major record labels and whose music is targeted at mainstream audiences. However, our study also shows that genre spanning has no negative, and even positive consequences for musicians produced by 'independent' record labels and who aim at specialized audiences. This finding thus corroborates DiMaggio's theory that art worlds might vary in terms of how strongly they reinforce genre categories.

The Dynamics of Categories

How do classification systems in popular music develop over time? Using DiMaggio's framework, the classification system of popular music could be described as showing trends in the direction of becoming more differentiated, less hierarchical, less universal, and more weakly bounded. The genre diversity, for example, seems to have increased considerably in recent decades and the field has become associated with a plethora of genres – especially those fields such as electronic dance music (which according to some counts consists of more than 300 subcategories) that have absorbed a large number of newcomers. This is on the one hand simply the result of the cumulative development of new genres, but also signals changes in the institutional logic of the recording and radio industry that have focused on more and more specialized genre niches. The way hierarchical boundaries are drawn within the field also seems to have changed. Until the mid-1980s, hierarchical distinctions between 'serious' and 'authentic' rock music and 'frivolous' commercial pop were more firmly based on the application of the principles of distinction that mirrored the boundary between 'art' and 'commerce.' In contrast, the contemporary field of popular music apparently is characterized by an 'intermediate aesthetic,' which combines commercial and artistic values. Genre boundaries have apparently also weakened. The rise of hybrid genres have been the outcome of the search for artistic innovation, which especially in the more autonomous sectors of the field, have been valorized rather than penalized, as we described in the previous section. Finally, the universality or consensus could also be said to have weakened, as a result of the increased differentiation in the field. As mentioned, one of DiMaggio's (1987: p. 448) propositions suggests that differentiation leads to loss of universality. People will, in other words, find it easier to agree on broad categories such as 'rock,' 'country,' 'rap,' rather than on very specific categories such as 'neoelectro' or 'futuristic breakbeat.'

To study whether these dynamic changes occurred in the *cognitive* classifications systems of critics, van Venrooij (2009) compared the meanings that critics associated with different genre terms between 1985–86 and 2004–05. By coding and identifying the various 'aesthetic codes' used by critics to describe and evaluate musical characteristics, this research was able to model the position of genres in an 'aesthetic discourse space.' By analyzing relations of similarity and difference between genres in this discourse space, the cognitive classification system of reviewers could be visualized.

The analysis of the relational structure of the classification system in 1985–86 and 2004–05 reveals that – in the way critics interpret and associate aesthetic elements with genres – the boundaries between genres have weakened. In general the overlap between genre categories increased, and more specifically the genre categories of 'pop' and 'rock' became more similar and synonymous. These two genres were also joined by 'R&B' and 'hip-hop' in the core of the classification system, suggesting a blurring of boundaries between these often socially differentiated categories, and signaling the movement of hip-hop into the center of the popular music field. This analysis also allowed the comparison of genres in their 'fuzziness' over time. For instance, jazz as a category seemed to hold relatively specific meanings for critics in 1985 but became a much more general and broadly defined category in 2005. Funk, on the other hand, went from a fuzzy category in 1985 to having more restricted meaning in 2005. Hence, this type of relational analysis of critical discourse can help assess changes over time in the meaning of categories.

To model the 'discourse space,' van Venrooij (2009) made use of the ecological notion of a multidimensional space – or Blau space. Although this research used ecological ideas to *describe* and model cultural classification systems, the use of ecological theory also holds the promise of possibly *explaining* changes in classification systems. Ecological theory – as applied to organizational forms – assumes that 'forms' occupy niches and compete with each other in a bounded resource space. Regions within this resource space have limited 'carrying capacities' and can only sustain a certain number of forms until they are saturated. New forms therefore develop within unsaturated niches that already contain similar forms to increase their 'legitimacy' but this 'emulation' turns to 'differentiation' when the 'carrying capacity' for certain niches is reached.

Drawing on this ecological approach to model how cultural forms, such as genres, are positioned in a bounded 'aesthetic space' may enable researchers to determine whether the dynamics of genres also follows ecological mechanisms. For example, do new genres emerge 'nearby' existing genres – where 'nearby' indicates similarity in terms of aesthetic conventions, or do existing genres change over time in their characteristics by adopting element from 'unsaturated' areas in the aesthetic space? This would thus allow the analysis of *endogenous* mechanisms of cultural change, which might occur through processes of mutual orientation and differentiation among actors within the field, mediated by the information provided by critics, magazines, and journalists.

Conclusion

The work of Paul DiMaggio has stimulated much interest in the study of classification systems. Although his theory was

predominantly developed to account for the rise and fall of the high culture system in the United States, here we have presented recent work that shows the usefulness of his thinking to the study of classification systems in popular music. This overview has, of course, not been exhaustive. Many more examples of research on classifications in popular music could be given. Here we have focused on our own contributions to this literature concerning the cross-national variations in the position of popular music in the cultural hierarchy, the construction of homologies between social and symbolic boundaries, and the consequences of boundary crossing and changes in the meaning of genre categories.

Abstract

This article covers the use of classification in the social sciences. Although in the past this tool was considered more suitable for the natural sciences, it has been applied to social phenomena more recently. The fundamental goal of classification is to find structures common to a group of objects, using properties to classify the objects into subgroups based on the similarity of their properties. This article details each step in the classification process and concludes with a discussion of how to evaluate a classification.

Classification is the assignment of objects to classes. For example, an educational researcher might want to establish a taxonomy of teaching styles that covers all possible approaches to teaching. A psychologist studying personality might be interested in whether children can be grouped into categories according to their patterns, or profiles, of personality traits. A sociologist might be interested in whether certain combinations of characteristics of urban areas (such as average socioeconomic status, crime rate, and building types) occur much more often than other combinations. A biologist might want to study whether animals showing a particular phenotype have specific combinations, or patterns, of genetic codes. In all these cases, objects (such as teachers, children, urban areas, and animals) are classified based on their patterns of some observable characteristics (such as teaching behaviors, personality traits, city characteristics, and genes).

The task of classifying objects poses several problems. The objects to be classified, the properties based on which they are classified, and the way of assessing similarities among objects have to be specified. The aim is to identify individual classes, to decide how many classes are warranted, and to establish procedures for identifying which class each object should be assigned to. Eventually, the success of the classification system must be evaluated. There are problems associated with each of these steps, and different solutions have been suggested for each problem.

In a sense, this article re-creates the process of establishing and testing a classificatory system. First, we define the topic more precisely, clarify the terminology, and provide some examples. Then, we present an outline of the first steps in a classification process and discuss one of the most debated issues: What is the concept of a class? After this, we deal briefly with procedures for assigning objects to classes and with the – frequently neglected – question of how to evaluate the resulting classification system.

Definition of the Topic

Terminology

Depending on the research tradition, the objects to be classified into a system are called elements, cases, units, exemplars, specimens, or items. They are the sources or 'carriers' of properties, characteristics, or variables. These properties may be dichotomous or polytomous, qualitative or quantitative. A property can only be useful in a classification, if it varies within the set of objects, that is, if at least two different values (e.g., categories, states, and labels) on the respective property occur in the sample. When more than one property is used to characterize an object, the object can be described as a vector of values, a profile, a set of symptoms, or a pattern of features.

Sometimes, the data do not consist of objects and their properties, but of measures of relations between objects, such as their similarity, likeness, or belonging together. For example, a researcher might ask participants to rate the similarity between different politicians. The similarity ratings can then be used to classify politicians into groups. Based on this classification, the researcher can then study on which features people's perceptions of similarities between politicians are based.

The crucial assumption underlying classification is that objects are elements of a class, of a set, of a partition, or – in biology – of a taxon. In other terminologies, the terms 'category' or 'cluster' are also used. Classification is the process of finding classes and of assigning entities to these classes. The end product of this order-creating process, however, is often also referred to as 'classification.' To stress this distinction, the term 'classification system' can be used for the end product, although in clinical psychology and biology the word 'taxonomy' is more common. Identification is the assignment of a specific case or object to (usually only) one of the classes.

Limits of Discussion

In studying classification in the behavioral and social sciences, we have to distinguish between two questions. (1) What theory and empirical evidence are available about how people classify objects? (2) What theories and methods are used to create classification systems? The first question will not be dealt with here (*see* Concept Learning and Representation: Models). The second question refers to the formal and empirical procedures used for defining classes and the rules that have evolved for assigning cases to classes. This second question is what concerns us here; it will be discussed from a conceptual rather than a statistical point of view. For more statistically-oriented discussions of classification methods, *see* Statistical Clustering; Mixture Models in Statistics.

One commercially 'booming' application of classification that this article does not refer to is in biometric authentification. The aim of these methods is to use combinations of characteristics of individuals to uniquely identify each individual. Thus, conceptually, the task is to assign one of very many cases into a class, when there might be as many cases as classes. In this process, an observed pattern of features, or even an observed set of such patterns, is matched against a stored list of patterns. For example, DNA is used in this way in forensic criminology, as are records of the past *modus operandi* of individual criminals in detective work. This is, however a fairly unique example of classification, because the number of classes is intended to be equal to the number of cases, which is rarely the case in the social and behavioral sciences.

Purposes of Classification

The fundamental purpose of classification is to find structure. Typically, a large number of objects is reduced to a much smaller set of classes without too much loss of information about the objects. The data thus summarized allow objects to be identified, at least in part, through the class to which they belong. Specifying the boundaries describing a class has several advantages. One is that limits to generalization can be established, and another is that it becomes possible to generate predictions about how different classes are composed and how class membership relates to other variables.

Some Examples of Classifications

The most well-known examples of classifications are from the natural sciences, rather than the social sciences. A well-known, still used, and expanding classification is Mendelejew's *Table of Elements*. It can be viewed as a prototype of all taxonomies in that it satisfies the following evaluative criteria: (1) Theoretical foundation: A theory determines the classes and their order. (2) Objectivity: The elements can be observed and classified by anybody familiar with the table of elements. (3) Completeness: All elements find a unique place in the system, and the system implies a list of all possible elements. (4) Simplicity: Only a small amount of information is used to establish the system and identify an object. (5) Predictions: The values of variables not used for classification can be predicted (number of electrons and atomic weight), as well as the existence of relations and of objects hitherto unobserved. Thus, the validity of the classification system itself becomes testable.

Another successful classification system is biological taxonomy. Indeed, most attempts to formalize classification have some intellectual roots in this tradition (Sokal and Sneath, 1963). The result of such classification is frequently depicted as a 'phylogenetic tree,' today often the result of comparative genomics. In biological taxonomy, however, theory is not so strong as to warrant completeness, as in the *Table of Elements* (e.g., how should one deal with archaebacteria?). Moreover, the identification of a specimen requires information from morphology and sometimes from behavioral observation. In addition, the system abounds with nested criteria. Further, compared with physics, predictions of future developments, or of 'missing links' in biological taxonomy are vague. However, the classes of the phylogenetic system are still useful because, at the very least, they indicate boundaries to generalization.

In the behavioral and social sciences, hundreds of classifications are published every year. Noteworthy examples are Bloom's taxonomy of educational objectives (Krathwohl et al., 1964), as well as the *DSM* (*Diagnostic and Statistical Manual of Mental Disorders*) and *ICD* (*International Classification of Diseases*) classification systems used in psychology and psychiatry. None of these systems have been formally derived, however. Instead, they were generated based on 'experience.' The resulting classes are so heterogeneous that they acknowledge many exceptions. Also, a phenomenon called 'comorbidity' shows that these classification systems are not optimal yet. It refers to the simultaneous existence of two or more disturbances in the same patient. If comorbidity is the rule rather than the exception, then the classification system loses plausibility and practicability.

Preparing the Basis of a Classification

Selecting the Cases

In the beginning of the process of developing a classification, two main questions arise: (1) Which elements are to be differentiated in a classification? One searches for a list (complete, if possible) of cases to be classified. This list is called the 'extension' of a classification. (2) Which properties characterize the cases? The list of these properties is called the 'intension' of the classification. The answers to these questions already determine, in part, the results of the classification. To quote Hartigan (1982: p. 2): "Clearly, the selection of variables to measure will determine the final classification. Some informal classification is necessary before data collection: deciding what to call an object, deciding how to classify measurements from different objects as being of the same variable, deciding that a variable on different objects has the same value." Sometimes, no well-defined population of objects is available from which to sample, and a preliminary selection has to be made intuitively. In such cases, future applications of the classification system may result in more or different classes from those originally obtained.

Specifying the Properties

The question of feature selection (selection of the properties on which the classification will be based) arises at two points in the process of classifying. First, as mentioned above, it arises at the very beginning of the process. The second opportunity to select properties comes when an established procedure is tested for identification. This problem is very similar to one in regression analysis: Which variables should be retained because they discriminate best, between the classes (see Pankhurst, 1991). Even if computational problems do not play a role, use of too many properties can still be problematic, particularly if measuring these variables is expensive or dangerous. In both instances of selecting properties, reliability is a very important issue. With decreasing reliability of the measurement of the properties, the identification of classes becomes more difficult.

Another important question is whether the values of the properties should be transformed before searching for classes.

The results of most classification procedures will be influenced by transformations. If differences in variability between the variables are of substantive importance, no transformations that equate variability across variables should be used. The use of transformations is also called 'a priori weighting.' '*A posteriori* weighting,' on the other hand, refers to cases in which different variables are given different emphasis in the identification process.

Especially in routine applications, a good strategy for selecting properties to be retained in the final classification might be to find a minimal set of variables sufficient to discriminate between all the classes. Relative to the set of all variables, the minimal set may not be unique. If this is the case, one will often prefer a set with few practical problems, and replace properties and take other aspects, such as minimization of costs, into account (see Pankhurst, 1991 for an algorithm).

Determining the Similarity

After the objects to be classified and their relevant properties have been selected, the similarity between objects is determined. Similarity is a key concept in classification. As was mentioned earlier, there are two basic ways to obtain similarity measures: The researcher can either collect similarity judgments from participants, or derive similarity measures from the empirical co-occurrence of properties. Methods for obtaining similarity judgments in the context of the first approach, 'similarity in the eyes of the participants,' are discussed in the context of data theory (Coombs, 1964). 'Proximity' measures can also be derived from confusion or generalization data, association probabilities, substitutability ratings, sorting procedures, and so on. The second case, 'similarity in the mind of researchers,' amounts to comparing the feature patterns of objects and describing the similarity between objects using *similarity coefficients*. A large, and still growing, number of these coefficients exist, and monographs on classification devote considerable space to them. Therefore, the choice of one particular coefficient should be explicitly justified. An analysis of the metric properties of coefficients is given by Gower and Legendre (1986). To choose a coefficient, one may refer to their axiomatic foundation (Baulieau, 1999).

Another important distinction in the selection of similarity coefficients refers to 'negative matching' i.e., deciding whether to include observations stating that two objects agree that a property is absent rather than present; that is, whether similarity between two objects in the absence, rather than the presence, of a property should be included in the similarity measure. Jaccard's (1908) coefficient excludes negative matchings.

Although most classification methods make use of similarity information, clustering models exist that do not refer to similarity. Another aspect that might be taken into account is the concept of similarity used: Why only use pairwise co-occurrences, and not higher-order contingencies (Daws, 1996)?

Establishing a Classification

After a measure of similarity has been selected, the next step is the actual classification of the objects based on the similarities between them. Formally (e.g., Biggs, 1999), classes can be thought as equivalent to (1) partitioning a set into subsets, (2) classifying a set of objects, and (3) distributing a set of objects into a set of 'boxes.' These various perspectives differ markedly in their implications for classification. For example, in most mathematical conceptualizations, an element is classified into exactly one class. Some clustering procedures, however, allow for residual elements, which are not considered clusterable.

Depending on the approach to classification that a researcher has chosen, certain considerations and precautions are necessary. For example, similarity judgment data may not fulfill some necessary assumptions; generally, related objects are to be located in the same class. The relationship xRx when 'x is related to x' has the properties of reflexivity: xRx, symmetry: $xRy \rightarrow\!\!\!\rightarrow yRx$, and transitivity: xRy and $yRz \rightarrow\!\!\!\rightarrow xRz$. These are the properties of an equivalence relation. If the empirical data are similarity judgments, they do not necessarily fulfill this relation. Some properties of this relation can be tested statistically. Another important consideration applies if the objects are classified by using rules referring to features. In such cases, these rules need to be free of contradictions (for a test, see Feger, 1994).

Only a few substantive theories in the behavioral and social sciences allow one to deduce the number and kind of classes needed to describe a given range of phenomena. Therefore, in many cases inductive procedures have to be used to generate classes. For this, one needs a concept of what constitutes a class. Many researchers apply inductive classification methods without ever considering explicitly the class concept that their method implies. The following part of the article gives a brief discussion of the class concepts implied in frequently used methods for finding classes. The list is not complete, and the 'cluster analysis proper' dominates all other approaches, because of the frequency of its use.

Before discussing class concepts in detail, one more general distinction needs to be made. If classes are defined by properties of objects, two levels of definition can be distinguished. A general definition specifies the relationship between the properties and the classes. Specific definitions provide detailed translations of the general definition into formal operations for assigning the objects to the classes. Obviously, there can be many different specific definitions. General definitions can be ordered by the kind and amount of variability they allow among objects within the class. There are two general positions with respect to within-class variability. The 'monothetic' position (Sutcliffe, 1993) assumes that a class is defined by one or a few necessary properties. The 'polythetic' counter-position (Gyllenberg and Koski, 1996) assumes that some properties of a specified total set, not necessarily the same for every object, are sufficient. According to this position, a property is shared by most, but not necessarily all objects of a given class. Proponents of the monothetic camp tend to stress that some properties are more important than others, and that these properties should be used to establish the classification. The opposite position assumes equal importance of all properties. As a third type of general definition, one may add definitions referring to a 'prototype,' that is, the most typical example of a class or a hypothetical mean object. In this last case, 'closeness' or similarity decides about class membership, and the prototype may be defined with or without allowing for variation in its properties.

Given properties as the base for a classification, the actual observations often are represented as a data matrix containing, for example, the objects as the columns and their properties as the rows. The cells of the matrix contain either the values '0' or '1' to indicate the absence or presence of properties, or they contain frequencies, durations, intensities, or symbols (in the case of qualitative polytomous items) that indicate the type or degree of the respective property in the respective object. As this enumeration shows, the procedure can accommodate data of all scale types. The goal now is to find a 'feature by classes' matrix, called – corresponding to its purpose – the reference or identification matrix, or simply 'a classification.'

Concepts of Classes

Cluster analysis proper. When authors (e.g., Everitt, 1993) illustrate the concept of a cluster, they often use two-dimensional graphs to show the clusters as clouds of points (representing the objects). The clouds can have various forms; generally there are 'gaps' between the clusters that contain no data points, so that the clusters are isolated from one another. While such explanations of the cluster concept seem intriguing as they invoke classical 'gestalt' concepts, it is important to remember that the properties of (good) figures are defined by several 'laws,' not just one or two axioms or rules, as in cluster concepts.

Helpful as visualizations are, the more general definition of a cluster does not refer to any particular conception of space, be it dimensional, metric, or Euclidean. Set theory defines a cluster as the maximal subset of elements for which proximities within this subset are larger than between any elements of the subset and elements not contained within it. As was discussed above, proximities are information about the extent to which objects 'belong together,' and could be expressed in many different ways, for example, as similarities, distances, ranks, or binary information about set membership. More than one subset may exist; subsets may be disjointed or overlapping; and they may or may not be hierarchically ordered. Given this very broad conceptualization, social scientists have access to a large number of clustering procedures. The large number of options reveals that no 'one and only' definition of a cluster can be found. Presumably, the availability of so many approaches is one reason for the paucity of comparative studies on methods of clustering.

Clustering procedures can be classified as 'leading to a structure that is either hierarchical or non-hierarchical.' The most frequently applied classification procedures are hierarchical, disjointed, and provide exactly one class for each object. The best known hierarchical procedures are agglomerative; that is, in a series of partitions they successively and with increasing dissimilarity, fuse the objects into classes. Each step provides a set of classes, from which the researcher has to make his choice. Once a fusion is made, it is irrevocable, so the early fusions should be very reliable. *Additive clustering* (Shepard and Arabie, 1979) is a hierarchical partitioning allowing membership of objects in any number of classes. Here, the classes might be interpreted as properties (Lee, 1999).

The cluster concept treated thus far is based on similarity as formally represented either in a space or by set theory. A close relative is prototype theory, popular in cognitive research. A prototype can be defined as a vector of values of selected properties; usually a list of cases as exemplars of this prototype is also available. One fundamental assumption of the prototype-oriented approach can be formulated as follows: If there is high similarity among a set of patterns, these patterns are also similar to an observed or inferred prototypical pattern. An inferred pattern could, for example, be the vector of mean values. This pattern has high or maximal similarity to every other pattern. The idea of inferring the prototypical pattern from the data forms a bridge to the similarity-based conception. But the researcher has to be more active in abstracting and defining a specific instance as the prototype.

Contingencies of higher order than similarities between the properties are exploited in some other generalizations of the concept of similarity-based clustering, such as Configural Frequency Analysis (Krauth and Lienert, 1973) and Pattern-Analytic Clustering (McQuitty, 1987). For example, Configural Frequency Analysis identifies combinations of properties that occur more often than expected from some specified base model.

A recent trend, increasing in strength, is to use mixture models for clustering. The original purpose of these methods was to base classification on a model that allows for inference-statistical treatment. But they have since found wider purposes. The basic idea of mixture models can be illustrated using the following example: Assume that a sample of measurements of body height is drawn from a human population. While it is known that all the cases are male or female, gender is not recorded for individual respondents. It is, however, possible, based on the distribution of heights in the total sample, to estimate the coefficients of the separate height distributions for men and women. This is done by interpreting each measurement as a sum of weighted height measurements for women and for men. These weights are the probabilities for each measurement to be from a man and from a woman. "Thus the density function of height has been expressed as a superposition of two conditional density functions; it is known as a finite mixture density." (Everitt, 1993: p. 110).

Mixture models are based on a 'space' concept rather than a 'similarity' concept; clusters are regions of relative point densities in this space. The assumptions for mixture models are comparable with those of the general linear model: cardinal scale level and multivariate normal (or similar) distributions of the data. A comparatively common mixture model for categorical data is Latent Class Analysis (De Soete, 1993).

To conclude this classification of class concepts, one further concept needs to be mentioned. This conception, models for block structure, is close to the raw data matrix and the Aristotelian tradition. A block is a maximal rectangular submatrix combining some objects and some properties with the same (or similar) values in the cells of the data matrix. The scale level of the values is not fixed, and the similarity concept is not invoked in the analytical procedure. In a block, the set of partially similar objects corresponds to the extension of a concept or class. The set of partially similar properties corresponds to the intension. The symmetry in the definitions of intension and extension is fully exploited and preserved (see Feger and De Boeck, 1993).

Evaluation of a Clustering Result

Although model evaluation is only a part of the overall evaluation of a classification (see Section Evaluating a Classification), it is an important one. As Dunn and Everitt (1982: p. 94) state: "Since clustering techniques will generate a set of clusters even when applied to random, unclustered data, the question of validating and evaluating becomes of great importance." Jain and Dubes (1988) classify the criteria of validation as follows:

> External criteria measure performance by matching a clustering structure to a priori information …. Internal criteria assess the fit between the structure and the data, using only the data themselves … Relative criteria decide which of two structures is better in some sense, such as being more stable or appropriate for the data.

Considerable progress has been made in internal statistical cluster evaluation. Statistical procedures exist for testing the existence of 'natural' clusters, for testing the adequacy of computed classifications, and for the determination of a suitable number of clusters (see, e.g., Bock, 1996). A very plausible way to evaluate any solution, independent of the clustering approach used, is to reproduce, or 'derive,' from the solution, all information that the solution gives about raw data that would fit with the solution, and then to compare this information with the actual raw data.

Procedures to Assign Cases to Classes

Procedures to assign single cases to classes are needed for two purposes. One purpose is to assign newly observed cases to the classes of an already existing classification. The other purpose is to evaluate a classification by taking 'old' cases from the original sample on which the classification was based, and checking which class they would be assigned to. In both cases, the question is: Into which class should the case be placed? In practice, experts (e.g., physicians) are often consulted for the answer of this question. In other cases, numerical procedures ('automatic classification') are used. Here, the properties may be used, either sequentially, as in a diagnostic key, or simultaneously by some type of matching between the case and the existing classes (see Dunn and Everitt, 1982; especially on diagnostic keys). Quite often, as identification with certainty is impossible "either because too many characters are variable within taxa or because all assessments of character states are subject to error, probabilistic identification methods are often used" (Dunn and Everitt, 1982: p. 112). Of the probabilistic procedures, the Bayes approach (*see* Bayesian Statistics) and discriminatory analysis (*see* Multivariate Analysis: Classification and Discrimination) are especially well known.

Other placement rules can be used if they are transparent, unambiguous, and do not lead to contradictions. For example, the principle of 'nearest neighbor' computes the distances of a new pattern to all existing classes. It assigns the new case to the class to which the distance is shortest (for details and other rules, see Looney, 1997). Rules may also include options such as rejecting a case as 'not classifiable' or postponing a decision until more information is available. Most rules currently applied are compensatory, but rules could also be disjunctive or conjunctive, requiring at least one value to reach a high amount, or all values to surpass a given minimum (Coombs, 1964).

Different rules lead to different results, especially if the classes vary in their a priori probability, if the distributions and covariances of the variables are very different, and if the number of observations is small. The single most important criterion for evaluating an assignment procedure is the number of correct classifications. But this 'apparent error rate' is optimistically biased, because it does not take into account the probability of correct assignments by chance. If base rates of class membership are known, the predictions have to perform better than the base rate (Pires and Branco, 1997).

Evaluating a Classification

While every step of the classification process can be evaluated (Milligan, 1996), two stages have received special attention: the evaluation of class definitions and of the identification procedure. Both have been mentioned previously. There also exist procedures to evaluate the overall performance of a classification system. The main method is 'cross validation,' using a new sample of data comparable to the old one, or splitting the original sample randomly into two halves and using one half to evaluate the classification obtained in the other half.

Another way of evaluating the results of a classification process is by comparing the results of using different classification procedures. Usually the researcher has several choices in the classification process, and is not forced by theory to select just one option. Examples include multiple options about the selection of cases and variables, of similarity coefficients, of clustering models, and of identification rules. With computers, it is easy to try several combinations of such choices. Confidence that the classification captures substantial information in the data grows with the amount of agreement in the results from different combinations of choice options (for the evaluation and comparison of solutions, see Everitt, 1993). To aid the interpretation of the resulting class structure, Milligan (1996: p. 346) suggests deliberately adding 'ideal types,' that is, characteristic patterns constructed by the researcher, to the data, and to assess what clusters these patterns are assigned to.

Can a classification be wrong? In most cases, a classification is just a systematic description, and as such, may, or may not, be useful. New observations may require changes in the classification. But if there exists a theory about the definitions of the classes, and the theory is strong enough to allow for specific predictions, then these predictions can be falsified and/or lead to revisions of the classification system.

Conclusions

More in the past than in the present, opinions fundamentally critical of the possibility of classification in the social sciences have been expressed. For example, Galt and Smith (1976: p. 58) stated: "Because they usually lack measurable dimensions, social entities are difficult to classify, and any given system of classification will inevitably be arbitrary." Indeed, numerical classification definitely requires measurement, or more generally, the interpretation of observations as variables.

Indeed, every variable is itself a classification, defined as a set of disjointed, exclusive and together sufficient classes, and the 'categories' of variables are referred to as their values. Without variables in this formal sense, one might consider a heuristic equivalent in abstraction from, and ordering of, observations: the 'ideal type,' as introduced by Max Weber.

Variables used to establish a classification may be discrete or continuous. For a classification to be justified, the frequency or density distributions of the properties should not be equal distributions, but show one or several peaks. Then, when the joint distributions of more than one variable are considered, some combinations of values may be more frequent than other combinations, perhaps even more frequent than would be expected based on the marginal distributions. This is one of the fundamental phenomena enabling the formal definition of classes.

While classification is a 'process,' the temporary result is a 'structure.' Dynamic aspects, such as the development of a property and other trends and changes, might be included in the definitions of variables. This does not, however, make a formal classification a process model. In this sense, classification is static. It temporarily fixes the – sometimes turbulent – streams of information. Changing a classification means the (re-)interpretation of some substantive area.

Abstract

The study of classifiers was concerned at first by classification systems in the nominal domain (with systems labelled numeral, noun, genitival and verbal classifiers according to their morphosyntacticloci), and only later with classifiers in the verbal domain (with verb classifiers). Beyond the spoken modality, classifiers exist in sign languages and Egyptian hieroglyphs. To account for the great variety of individual systems, a multidimensional approach is adopted. This approach includes an inventory of forms and a semantic profile of the system, the classificatory scope of individual classifiers, and the system's origin and stage of evolution. Pending are issues of lumping versus nonlumping of classifier and other types of systems, and a terminology to handle the great variety of systems.

In the literature concerned with linguistic categorization systems, the term 'classifiers' is actually used in two ways, either for a great variety of systems or for a much narrower range of such systems. The wide-scope approach, called here the lumping position, finds its justification in the multiple ways in which many linguistic categorization systems share some similarities of either forms or semantics. The narrower approach taken here, or nonlumping position, means to isolate a particular set of those systems and to only use the term 'classifiers' for them. This set is characterized by its nonconcordial morphosyntactic nature, its not being involved in lexicogenesis (or creation of new words in the lexicon), its being of clear lexical origin and persistent semantic motivation, and its being subject to specific discourse-pragmatic conditions of use. In this narrower sense of the term 'classifiers,' there are no classifier systems in Indo-European languages and the most widely known exemplars of such systems are most likely the numeral classifier systems (see Gil, 2013), found in Asian languages like Chinese or Japanese (pp. 279–303), but also in America (see early study by Berlin, 1965). They are illustrated in **Table 1**.

History of Classifier Studies: From the Classics on …

Classifiers became of interest to general linguists in the 1970s, following proposals to capture their universal semantic properties. Three articles stand out as classics of the field. Adams and Conklin (1973) were the first to wade through much comparative data and to claim the existence of some universal semantic properties of systems of classification. They used primarily data from Asian numeral classifier systems and established the primacy of three basic shapes, semantic combinations of one of the major dimensional outlines of objects (1D, 2D, 3D) with a secondary characteristic of consistency and/or size, the primary shapes being 1D rigid, 2D flexible, and 3D full. They showed how these combinations of features were directly inherited from the most common lexical sources for the most basic set of classifiers, designating the primary elements of the physical world being handled for the survival of human communities, as shown in **Table 2**.

Denny (1976) was the work of a psychologist whose main contribution was the appealing proposal that what classifiers are 'good for' (the title of his paper) is to signal how humans interact with the world, as indicated by the organization of the semantic traits of classifiers into three kinds, those of 'social, physical, and functional interaction.' The 'social interaction' domain is that of animate entities of our world, principally fellow human beings, classified by sex, social rank, or other categorization schemata, as well as other entities such as divinities and other powers specific to a culture. The 'physical interaction' domain is the one of manipulatable and manipulated objects of the world classified along certain parameters linked to their nature, principally of shape. Finally, the 'functional interaction' domain is that of entities of the world being classified by the use to which they are put, such as food, clothing, or transportation, for instance.

Allan (1977) was the first typological study based on a broad database of 50 classifier languages covering different types of nominal classification systems. Although the reliability of the data was variable, there was still a remarkable overlap between the seven 'categories of classification' (material, shape, consistency, size, location, arrangement, and quanta) he proposed and Denny's (1976) three functional domains. Furthermore, two of Allan's original statements were of particular interest

Fruit	3D: round

for later discussions on the nature and purpose of such categorization systems. They were the note of a total absence of color classifiers, and of a constraint that the characteristics picked up in the classification system be perceivable by more than one of the senses alone, such as sight and touch, where sight means primarily perception of shape.

Several collective publications later expanded the field of nominal classification studies in general from various disciplines. Seiler and Lehmann (1982), Seiler and Stachowiack (1982) and Seiler (1986) report on the major typological project known as UNITYP, which studied the various techniques that languages have to capture the function of apprehending objects, including numeral classifiers and noun classes. The collection in Craig (1986a) covers various approaches from different fields, and includes articles on the acquisition, historical development, discourse function, semantics, and cognitive value of these systems. The collection in Senft (2000, actually based on a 1993 working conference) is a further elaboration of issues of typology, grammaticalization, and function of nominal classification systems.

Typology of Classifier Systems

While the first studies of so-called classifiers had a general tendency to overlook the existence of multiple types of classification systems, at some point linguists' attention turned to the typological characterization of classifier systems per se. The specificity of these particular systems was then considered at two levels: at one level the issue is to distinguish them from other types of classification systems, and at the other it is to recognize several subtypes among them.

Classifiers as One Type of Nominal Classification System

As argued early in Craig (1987) and worked out in more detail in Grinevald (2000), classifier systems can be identified as specific types of linguistic systems both on lexical and morphosyntactic grounds, although it is true that in some languages the different systems commonly share lexical sources and seem to be intertwined, as will be considered below.

In the lexical domain, classifiers may be distinguished from *measure terms and class terms* with which they are often either confused or consciously lumped.

All languages have lexical sets of measure terms, the expression 'measure terms' being used here as a cover term for what are strictly speaking measures and types of arrangements. Examples of English measure terms include actual measure terms such as a glass of water, a pound of sugar, a slice of bread, a sheet of paper, and arrangements such as a pile of books, a group of children, a line of cars. Class terms are sets of lexical items used in lexicogenesis; they participate in compounding processes of word formation that are functionally equivalent to derivational processes. English has class terms like '-berry' (as in strawberry, blueberry, boysenberry, gooseberry, loganberry), '-man' (as in mailman, policeman, garbageman), or '-tree' (as in apple tree, banana tree, cherry tree), for which the functional equivalent in French can be derivational suffixes, such as '-ier' (as in pommier 'apple tree,' bananier 'banana tree,' cerisier 'cherry tree').

Table 3 Different systems of overt linguistic categorization

In the morphosyntactic domain, classifiers can be distinguished from concordial systems such as *gender* best known from Indo-European languages and *noun class systems* of Bantu languages. Classifiers therefore are one among several systems of overt linguistic categorization of nominals as shown in Table 3.

Various Subtypes of Classifier Systems

Beyond distinguishing classifier systems from other systems of nominal classification, it is further necessary to acknowledge the existence of several subsystems of classifiers.

Craig (1987) and Grinevald (2000) proposed a typology based on the morphosyntactic locus of the classifier, on grounds of better reliability of this criterion over one of semantics. It was clearly conceived as a guide to fieldwork on yet undocumented systems of oral tradition languages. The proposal presented here stands therefore in contrast to studies where all systems are mixed in a lumping position, as was the case in Allan (1977) but also still in Croft (1994), for instance, in which discussions on universal semantics miss the specificities of the distinct systems in their more prototypical forms.

In the study of classifiers, which was first limited to the domain of nominal classification, i.e., the categorization of nouns, the numeral classifiers (numeral + CL) used in quantifying expressions were the best known and those considered as the prototype of classifiers (and are still considered that way by many). But three other subtypes of classifiers were later identified. From languages of Oceania linguists learned of genitival or possessive classifiers (poss + CL) as constituents of possessive constructions, and from languages of Mesoamerica and Australia came the identification of noun classifiers (CL noun), so-called for appearing with a bare noun and not linked to the expression of quantification or possession, although sometimes labeled generic classifiers because of their semantics. Finally, North American languages exhibited yet another type of classifier, labeled verbal classifiers (verb-CL) for being morphemes referring to nominal arguments inside the verb form, often linked to linguistic processes of incorporation.

These four major subtypes of nominal classification systems identified in the languages of the world are schematized in Table 4.

Table 5 gives sentence examples to illustrate these four major subtypes of classifier systems.

To the major noun/numeral/genitival/verbal classifiers shown in this diagram, one should add two much rarer secondary types that have been identified more recently, mostly in Amazonian languages, and have been found on demonstratives and locative adpositions (Aikhenvald, 2000).

Table 4 Loci of major subsystems of nominal classifiers

2.	**Numeral classifiers**; Ponapean (Rehg, 1981, p. 130)	a.	pwihk riemen pig 2+CL: animate 'two(-animate) pigs'
		b.	tuhke rioapwoat tree 2+CL: long 'two(-long) trees'
3.	**Genitive classifiers**; Ponapean (Rehg, 1981, p. 184)	a.	kene-i mwenge CL-GEN.1 food 'my(-edible) food'
		b.	were-i pwoht CL-GEN.1 boat 'my(-transport) boat'
4.	**Verbal classifiers**; Cayuga (Mithun, 1986, pp. 386–388)	a.	ohon'atatke: ak-hon'at-a:k it-potato-rotten past.I-CL-eat 'I (potato-)ate a rotten potato'
		b.	skitu ake'-treh-tae' skidoo I-CL: vehicle-have 'I (vehicle-)have a car'

Arguments for Subtypes

The existence of different subtypes of classifiers was argued on several grounds (as in Grinevald, 2000). First is the characteristic of different loci for the classifier, as mentioned above in Table 4, with a specific inventory for each locus. Second is the fact that several independent systems can co-occur in the same language with different inventories and different semantics in different morphosyntactic loci. Such is the case of the coexistence of numeral and genitival (or possessive) classifier systems of Micronesian languages like Ponapean, as exemplified above in Table 5. The third argument is semantic, and relies on a strong correlation between the major morphosyntactic subtypes of classifiers presented and their semantic profiles, i.e., the semantic basis of their categorizing principle. It is not a question of all or nothing, since, as discussed below, the dynamics of such systems allow for much variation and overlap, but of strong tendencies. Concentrating on the categorization of nonhuman entities (and borrowing from Denny (1976) the notions of physical and functional properties) the following pattern can be seen: physical properties such as shape seem to be the dominant semantic parameter of numeral classifier systems, functional properties such as food and transportation the major one of genitival classifier systems, while material and essence of objects constitute the major concern of noun classifier systems, as schematized in Table 6.

Two notes of clarification about these correlations between semantic profiles and subtypes of classifiers are needed. One is that the numeral classifier systems have two kinds of elements within the same inventory and in the same slot, known as mensural (two-truck loads of/lines of trees) and sortal (two-long trees) elements, and that only the sortal ones are considered here. The other is that no particular correlation seems to hold between verbal classifier subtype and semantic profile (as illustrated in the Cayuga examples of Table 5).

While the first studies of the phenomenon of classifiers were restricted to the domain of nominal classification, other systems were identified that classified verbs through verb semantics, first on the basis of languages of Australia (Schultze-Berndt, 2000; McGregor, 2002), but also in parts of

Table 6 Different semantic profiles of subtypes of nominal classifiers

Subtype	*Semantic profile*	*Examples*
Numeral classifiers	Physical categories	One-LONG RIGID canoe; Two-ROUND oranges; Three-FLAT FLEXIBLE blankets
Genitive classifiers	Functional categories	My-VEHICLE canoe; Your-EDIBLE fish; His-DRINKABLE potion
Noun classifiers	Material/essence categories	(a/the) WOOD canoe; ANIMAL (woollen) blanket; PLANT coffee (drink)

Table 7 Verbal versus verb classifiers

Verbal CL (classifier of patient object)	*Verb CL (classifier of verb semantics)*	
a. I [LONG RIGID]-put a knife on the table	c. You shout-[SAY] to me	(Intransitive)
b. I [VEHICLE]-have a canoe	d. Put-[DO] a knife on the table!	(Transitive)

Latin America (Dickinson, 2000). The contrast between verbal (locus) and verb (domain and locus) classifiers is outlined in Table 7 where in (a) the classifier attached to the verb refers to the characteristic shape of the knife, while in (b) the classifier categorizes the semantics of the verb itself.

Schultze-Berndt labels these verb classifiers generic verbs. They constitute a closed class that take verbal inflections and are accompanied by so-called 'coverbs' corresponding to the verb class of European languages but including also adverbs. Table 8 shows three such verb classifiers.

The inventory of these verb classifiers (as in Schultze-Berndt, 2000, pp. 402–404) contains 26 elements, constituting the categorization of events given in Table 9.

Table 9 Inventory of classifier VERBS in Jamingjung

	Semantics of categorization	*CL of intransitive verbs*	*CL of transitive verbs*
a.	Location, existence, possession, and change of locative relation	BE, FALL	HAVE, PUT
b.	Translational motion	GO, COME	TAKE, BRING, LEAVE, APPROACH, FOLLOW
c.	Contact/force	–	HANDLE, HIT, CHOP, KICK/STEP, POKE, BITE, THROW
d.	Burning, cooking	BURN	COOK
e.	Polyfunctional	–	SAY/DO
f.	Caused change of possession	–	GIVE, TAKE AWAY
g.	Other major verbs	–	SEE, EAT, MAKE

Schultze-Berndt, E., 2000. Simple and complex verbs in Jamingjung: a study in event categorization in an Australian language, Ph.D. thesis, University of Nijmegen, pp. 402–404.

Classifiers in Other Modalities

Furthermore, the discussion of classifiers has been extended to languages of other modalities, such as visual modalities, dynamic for sign languages, and static for hieroglyphs, but both interesting for their iconic nature. Emmorey (2002) is a collection of articles on the phenomenon of classifiers found across the sign languages of the world, shows that their dominant type is of the form of verbal classifiers, discussed in sign language literature under the label of classifier constructions. It has also been argued that some sign languages, such as Swedish sign language, exhibit not only verbal but also noun classifiers (Berman and Wallin, 2003). The latest addition to the discussion of classifier studies comes from the writing system of some ancient languages, such as Ancient Egyptian and Sumerian. Goldwasser (2006) argues that the elements of the Egyptian hieroglyphic writing system known in the literature as 'determinatives' (Champollion, 1836) can be reanalyzed as classifiers. Goldwasser and Grinevald (2012) further specify that, on closer inspection, this particular system of classifiers can be shown to resemble known classifier systems of oral languages although it presents the unique characteristic, not described for other languages as yet, of combining within one system the classification of both nouns and verbs, in their respective morphosyntactic loci with their expected semantic profiles (categorization of humans, animals, and inanimates of the Egyptian culture vs categorization of types of events). Table 10 offers a sample of such coexisting noun and verb classifiers.

This system sometimes also applies to other word categories, such as adverbs and adpositions more rarely attested in classifier systems of the world (but found in Australian Jamingjung verb classifier system too). It would seem that what appears as a mixed noun and verb system is most likely a natural phenomenon of classification of a root system. Roots are a central concept of this language in which it may prevail over that of word categories (noun and verbs) of prime importance in Indo-European languages. The analysis of determinatives as classifiers is not yet accepted by all Egyptologists who do not consider it as part of the language, on the ground that the system is restricted to the hieroglyphic writing system and appears not to have been part of the spoken language. This is evidenced by the fact that when hieroglyphs were transcribed into Coptic writing these classifiers were ignored. But the system is so strikingly similar in its categorizing schemata to classifier systems of spoken languages that drawing the parallel argues interestingly for the cognitive power of such systems, with their mix of universal and language specific categorization processes, independent of the modality of expression.

Therefore, in the end, the variety of subsystems of classifiers is much greater than thought before, the classifier systems of

the major lexical categories of N and V attested in the languages of the world today being as presented in Table 11.

A Multidimensional Approach to the Study of Linguistic Classification Systems

One of the major challenges of classifier studies is not only that there is a great variety of classification systems, but that there is also great variability within the different types of systems and subsystems. These varieties are taken to reflect the intermediate nature of these systems as secondary linguistic systems of clear lexical origins, some borrowed, some native, and all at different degrees of grammaticalization. The multiple dynamics at work in those systems make the descriptive task onerous, but at the same time very productive when proceeding to comparative and typological work. It is of prime importance, therefore, to consider a number of dynamic variables, from synchronic and diachronic points of view, for any description of a specific system along the line of topics listed below.

The Inventory of Forms and Its Semantic Profile

Systems of classifiers vary greatly as to the number and the specificity of the classes that compose a system. The inventory of classificatory items can be small or large, from a handful to hundreds, with some systems open. The inventory generally has a dominant semantic profile, corresponding to one of the three functional domains mentioned (social, physical, functional).

The Classificatory Scope of Individual Items

The classes defined can vary from very simple homogeneous with transparent semantic motivation to very complex, heterogeneous ones. The latter are organized around a core of prototype elements to which others have been added through various means of extension, such as with the famous class of 'women, fire, and dangerous things' of Dyirbal (interpretation from Lakoff, 1986, 1987; or original analysis from Dixon, 1982). Another well-known example is the case of the Japanese numeral classifier [hon], used prototypically for long, thin objects but in modern times classifying telephone calls and baseball hits as well (Matsumoto, 1993).

The items of an inventory are therefore of very different classificatory scope. The most common classifiers categorize at some generic level (e.g., animal/plant or 1D–2D–3D or food/transport), while others, fewer, at a more specific one (e.g., a corn and corn product class next to a generic plant class), with the specificity going to the extreme situation of so-called 'unique' classifiers, meaning classifiers heading a class of just one item (e.g., 'elephant' or 'tiger' or 'crocodile' in a class of its own, next to an animal classe). These specific and unique

Table 11 Diversity of subtypes of classifiers (and sample languages)

classificatory items are particularly interesting for their cultural significance (as demonstrated for Jakaltek Popti' in Craig, 1986b). At the other extreme, the inventory of some systems also includes a totally desemanticized classifier, or default classifier, for any number of items with no semantic links (meaning something like 'a thing'). This default item is often traceable through time to some specific noun turned classifier (as e.g., bamboo in Chinese and papyrus scroll in Egyptian hieroglyphs).

Origins: Internal Development or Borrowing of an Idea and Areal Spread

Classification systems follow various paths of evolution. Some emerge language internally, from already existing lexical classification systems like class terms, and recycled lexical items of the language. Any classification system needs to be assessed further in the context of a common phenomenon of areal spread. The spread can operate either through the actual borrowing of a system, morphology included, or through the borrowing of the idea and motivation for the development of such systems with native lexical items. A well-known case of areal spread is that of the expansion of the original Chinese numeral classifier system into its surrounding regions (Bisang, 1999); more recent literature treats the spread of noun class and classifiers in the Amazon region (Seifart and Payne, 2007; Aikhenvald, 2012).

Age, Life Cycles, and Degree of Grammaticalization

Systems studied today vary greatly in age. Some are very old, such as the Chinese numeral classifier system or the Egyptian hieroglyphic system, while others can be argued to be only several centuries old, like the Q'anjob'alan-Mayan noun classifiers, or even much less for some of the recent sign language verbal systems.

An early proposal (Dixon, 1982; repeated in Dixon, 1986; echoed in Grinevald, 2000) had suggested a correlation between type of classification system in general and degree of grammaticalization based on comparisons of the better known systems of the time, i.e., Bantu noun class systems and Asian numeral classifier systems. However, new data on other noun class systems and classifier systems per se have led to the proposition of disconnecting the question of the degree of grammaticalization from the type of system. Guarding against some Eurocentric posture and the problem of considering as prototypical the first systems described, Grinevald (2002) argues against this correlation, on the basis of a sample of classifier systems of different subtypes. They include incipient to well-established systems of noun classifiers from the Australian (Sands, 1995) and American continents, and more or less grammaticalized numeral classifiers of Asian languages as well as very grammaticalized ones of Chibchan languages of Central America. In a similar vein, Grinevald and Seifart (2004) contrast incipient noun class systems of Amazonia to more grammaticalized Bantu noun class systems (which in fact exhibit more variability than acknowledged in the literature and can be very old, sometimes even decaying).

The parameters considered to establish the degree of grammaticalization of a system are as listed in Table 12.

The Productivity of the System

Independently of its origin, its type or its age, any system can be shown to be more or less productive, adapting or not to linguistic and cultural development by incorporating new items in its classification schemata. For instance, the Thai

Table 12 On the grammaticalization of classification systems

	Less grammaticalized systems	*More grammaticalized systems*
System properties	Do not classify all nouns (nonexhaustive)	Classify ALL nouns (exhaustive)
	Few classes if emergent, to very LARGE NUMBER of classes if fully developed	SMALLER number of classes
	OPEN and productive	CLOSED
Use	Possibility of assigning N to DIFFERENT CLASSES	N assigned to a UNIQUE CLASS
	Determined by speaker's pragmatic CHOICE	NO speaker VARIATION
	Varies in formal/informal contexts	No variation according to register
Morphosyntax	Not affixed to the noun	Possibility of marking on the noun itself
	INDEPENDENT constituent without fusion	FUSED with other grammatical categories (def, nb, case)
	No or limited agreement schema: marked for pragmatic purpose	Part of rigid AGREEMENT schemata (beware of effect of standardization; freer in speech!)

numeral classifier system, which is very old, is also very productive: it is open and adapting to the language of modern life, in contrast to the noun classifier system of Jakaltek-Popti', which is not very old, but seemed frozen and unable to cope with the classification of modern imports and products when studied in the 1970s (Craig, 1986b).

All these parameters of variation make it clear that no two classification systems, even of the same type or subtype, will resemble each other closely, although they remain comparable when caution is taken to factor in those parameters of variation. What is striking in fact, in the midst of the surface variation of all these classification systems in terms of origins and paths of evolution, is precisely their shared basic principles of semantic categorization of the world humans live in. In their classificatory schemata, made at once of cognitive universal patterns and cultural specificities, they are of great interest to various disciplines beyond linguistics itself.

Discussion

The situation in classifier studies today is that of a pervasive confusion about what is being discussed, due to unsettled issues of terminology (that persist even at the time of this writing).

Classifiers from a Lumping versus Nonlumping Position

As set out from the start, a primary issue to clarify would be the question of lumping all classification systems together (Aikhenvald, 2000, 2012; Croft, 1994; Seifart and D. Payne, 2007) or not lumping them and identifying a subset of systems called classifiers (the line mainly argued in Grinevald, 2000 inter alia). Much depends on an a priori positioning, clearly influenced by the nature of the data that individual linguists handle. The fact is that there can be overlap among systems, of lexical sources, of categorization schemata, when systems sometimes emerge one from another, while discussions of dynamics and levels of categorization can apply equally to both noun class and classifier systems. However, from a strictly linguistic point of view, a nonlumping morphosyntactic approach facilitates a concentration on the specificities of 'classifier systems' per se as one-place grammatical classification systems, and allows for better attention to their own varied subtypes, as shown above.

It is worth noting, in addition, that if all systems of linguistic categorization were to be called 'classifiers,' in a lumping approach, then another term would need to be invented for the particular set of classification systems labeled 'classifiers' in a nonlumping approach.

Further Terminological Issues

Independent of the lumping issue, some researchers question altogether the appropriateness of the term 'classifier' or the pertinence of talking of classification in general, since the term classifier can be seen as a misnomer indeed, if taken literally as necessarily implying classifying. The problem often raised is that of the phenomena of 'repeater' and 'unique' classifiers, where 'repeater' refers to a classifier that is a copy of a noun and 'unique' to one that heads a class of just one item, neither appearing to classify sensu stricto. But classification is far from the only or even, at times, the main function of classifiers, which lay important and diversified roles in discourse (as discussed in the collections of Craig, 1986a; Senft, 2000, for instance, and further explored in Contini-Morava and Kilarski, 2013).

The term classifier cannot be taken either as applying to a specific linguistic category, since there is so much variation along the parameters outlined above, so that no two systems are indeed the same. The appropriate way to use the term is therefore as a cover term, maybe best written in caps as some type of grammatical gloss, as CLASSIFIER, to signify its status of abstract comparative concept to permit a typological approach through the great language specific diversity of such phenomena locally described in family specific terms.

At a more local level, the terminological problem extends to the naming of the subtypes of classifier at two levels, the lexical domain of classification (of nouns or verbs, that could also be labeled nominal vs verbal classification) versus the morphosyntactic locus of the classifying element (again potentially either set of terms). But the present situation remains one of nonalignment of terms between these two levels which comes from the evolution of the discussions over time, from language particular descriptions to a more global view of all systems for typological purposes. The choice was made not to correct this problem in this article since one of its major goals was to report on the existing literature, but the task remains, particularly now that an even wider range of systems has been described, inviting another round of typological studies.

Another unsettled question of terminology is that of the labeling of the different levels of categorization identified, with alternative naming existing at each level identified. For instance, the most desemanticized classifier is called either 'default' or 'general,' while the most common one is called either 'general' or 'generic,' or even 'specific,' although some reserve the term specific for a lower level of categorization. Only the level of unique classifier is uniformly recognized and labeled. The most important point has been made, however, that classifiers define more or less heterogeneous classes, through processes of extension and progressive desemanticization of existing classifiers, with a very language specific selection of specific items of culture for special treatment.

Additionally, there is sometimes a confusion between two types of classifiers, where 'unique' refers to a classificatory function (of class contains of only one item), and repeater to the form of the classifier (whether full or truncated form of its lexical source, with no particular link to the process of classification). The nature of unique and repeater classifiers was illustrated in Table 13.

Table 13 Repeater versus unique in Jakaltek Popti'

CL		*Repeater*	*Unique*	*CL*		*N*
atz'am	'Salt'	+	+	*atz'am*	*atz'am*	'(The) salt'
metx'	'Dog'	−	+	*metx'*	*tx'i'*	'The/a dog'
ha	'Water'	+	−	*ha*	*ha'*	'The water'
				ha	*nhab'*	'The rain'
				ha	*pam*	'The/a lake'
				etc.		

Conclusion

The domain of linguistic classification systems is very rich and varied, marked by a fluidity across a number of possible systems which share their being secondary systems of lexical origin forming more or less grammaticalized systems. This article has concentrated on the systems known as classifiers in a nonlumping position and proposed a morphosyntactic approach to the typological study of classifiers, with the view of encouraging the linguistic description of as many new systems as possible. The lumping position has been taken more recently by linguists dealing generally with the intricate interweaving and overlapping of classificatory systems typical of many Amazonian systems, more focused on semantic similarities than on the structural specificities of the systems. Such a lumping position is also the approach of a general study of the functions of the different nominal classification systems: semantic, such as expanding the referential power of the lexicon; and discourse/pragmatic, such as establishing and manipulating the status of discourse referents (Contini-Morava and Kilarski, 2013). The challenge of accounting for the nature and specificities of linguistic classification systems persists, but interest in them remains high as they provide a unique window on issues of cognitive and cultural categorization, and, as emphasized here, on the dynamics of grammar-making. Language systems in other modalities, be they contemporary sign languages or ancient hieroglyphic writings have confirmed in recent times how essential linguistic categorization is for any type of human language.

This article is a revision of the previous edition article by P.W. Airasian, volume 3, pp. 1978–1983, © 2001, Elsevier Ltd.

Abstract

This article defines and discusses the essential characteristics of classroom assessment. Classroom assessment consists of procedures teachers use to gather information about student performance. This comprises both informal and formal techniques, aligned to learning objectives and used for documenting student learning (summative assessment) and improving student learning (formative assessment), as well as influencing student motivation. Characteristics of high-quality classroom assessment are presented, including validity, reliability, and fairness. Grading is also discussed.

Classroom assessment is a set of strategies, techniques, and procedures that teachers and students engage in to collect, evaluate, and report student achievement. It is a tool teachers use to gather data and information about how students are progressing in what they know and in the development of their skills. It is generally focused on K-12 education, although many principles are also applicable to higher education. Classroom assessment is used for a variety of purposes – to document what students know and can do, diagnose strengths, weaknesses, and misunderstandings, improve and enhance student learning, motivate students, assign grades, and provide feedback to parents. It is much more than 'testing,' although tests have been used extensively as one type of classroom assessment.

Classroom assessment is different from other kinds of assessments that are used in education. They are primarily controlled and used by classroom teachers, and are often unique to each class. Teachers use different types of classroom assessments on a daily basis, as well as over weeks or even months. A different type of assessment could be classified as *standardized*. Standardized tests have specific and set procedures, formats, and scoring levels, and are used for many students across different classes, schools, and states. They are often called *large-scale* tests. While there are many types of standardized tests that have been used for decades, including standardized achievement and aptitude tests, the most common ones now used in schools are externally prepared and scored accountability tests. Such tests are mandated by states and used to document student achievement at the end of the year. Psychological tests, such as personality tests, are also used with students, as are a multitude of other types of assessments that are used for research purposes.

Components of Classroom Assessment

There are five components of classroom assessment: purpose, learning objectives or targets, measurement, interpretation, and use. Purpose is the reason for the assessment, why it is given. This includes such uses as obtaining diagnostic information, providing feedback to students, documenting levels of achievement, motivating students, grading, reporting to parents, instruction, and, recently, preparation for taking accountability tests.

Learning Objectives or Targets

Learning objectives or targets are statements that define what students are expected to learn. Since the early 1990s the term *standards* has been used to designate what students should learn at different grade levels in each subject. It is important for these statements to be clear and reflect the range of content and skills to be emphasized, as well as the level of cognition required to demonstrate what has been learned. States have identified standards that are the basis for accountability tests. They tend to be broad, covering an entire year of learning. Objectives and learning targets are more specific and refer to what is to be achieved over short units of instruction.

The level of cognition or thinking needed for meeting learning objectives is a critical part of classroom assessment. Cognition can be very simple and consist of recalling or remembering something, or more complex in requiring knowledge utilization with skills such as application, analysis, reasoning, critical thinking, or evaluation of something (these are often called *higher-order* skills) (Marzano and Kendall, 2007). Educators often use Bloom's taxonomies to define levels of skills (Anderson and Krathwohl, 2001; Bloom, 1956), although there are others that reflect more recent research (e.g., Marzano and Kendall, 2007). As long as the objective is clear it will provide a sound basis for the assessments and how results will be scored.

Measurement

Measurement is the process of quantification of behavior or performance, the assigning of numbers to suggest a level of achievement. Measurement is used to differentiate levels or degrees of knowledge, understanding, and skills. There are many types of assessment that are used to enable the measurement process, including *selected-response* tests, such as multiple-choice, true–false, and matching, where students select an answer from choices that are provided, and *constructed-response* assessments, such as essay, papers, and projects, in which students must provide their own work without being given choices. The result of measurement is typically a score, reported as either a number, or a grade, or a level of performance.

Interpretation

Once a result of student performance is obtained it needs to be interpreted or evaluated to determine what it means. This involves the use of a variety of benchmarks and other information that assists teachers in making professional judgments about the meaning of the results. For example, what does achieving 70% correct on a test mean? Is this average, less than average, or even failing? Does it suggest an incomplete understanding of what was learned? Teachers' professional judgments are informed from their experience and guidelines, as well as from comparing students, and are needed to make correct decisions. 'Objective' assessments such as multiple-choice tests are objective only in the manner in which they are scored, not interpreted. There is still a need for interpretation.

Use

Use of the results should be consistent with purpose. Once results are interpreted teachers use them in many different ways, including grading, reporting to parents, planning subsequent instruction, and feedback to students.

Summative and Formative Classroom Assessment

Perhaps the most significant development in classroom assessment over the past two decades is the development of what is called assessment *for* learning, or *formative assessment* (Andrade and Cizek, 2010; Black et al., 2003; Stiggins, 2008). It is contrasted with *summative* assessment, which is used at the end of a period of student learning to document student performance, to show student achievement. Formative assessment is typically ongoing, with the primary purpose of enhancing student learning. While summative assessments tend to be formal, objective, and conducted only at the end of a unit of instruction, assessment *for* learning tends to be informal, occurring throughout and embedded in learning activities. Evidence of student learning is used by teachers to give students feedback and to make adjustments in their instruction. Learning is actively monitored as it occurs to help provide hypotheses about progress toward learning goals and objectives and instructional effectiveness. As such, formative assessment is integrated with instruction, rather than being something that occurs after instruction has concluded to provide a summative and static measure of achievement.

The goal of formative assessment is to improve student learning and motivation by enacting five essential steps:

1. Establishing criteria for evaluating student learning and understanding;
2. Collecting evidence of student learning and understanding;
3. Providing feedback to students on their progress toward reaching learning targets;
4. Involving students in self and peer assessments; and
5. Using instructional adjustments to help students learn.

Criteria are the elements of student performance that are important determinants of success. They are contained in student responses to evaluate progress toward meeting the learning targets; the dimensions or traits in products or performance that are used to determine level of understanding. For example, criteria to evaluate a persuasive essay could include the following criteria:

- Appropriateness of language for the audience
- Plausibility and relevance of supporting arguments
- Level of detail presented
- Evidence of innovative thinking
- Clarity of expression
- Organization of ideas

Criteria for an evaluation of graphic display of data could involve:

- Title
- Labels
- Accuracy
- Neatness

Once criteria are established and communicated to students, evidence of student understanding is gathered (Heritage, 2013). For some situations this could be structured as a pretest or pre-assessment, given to students before instruction is started. Pretests can be effective, as long as students are motivated to do their best. Other approaches to pre-assessment, such as giving students a short assignment or task and observing their performance, can be useful. During instruction, pre-assessment is often accomplished with the effective use of questioning or assigning short tasks. Verbal responses are evaluated, as are nonverbal indications such as facial expressions and body posture. Here the teacher needs to ask the right kind of questions, ones that engage and challenge students and elicit their thinking. These typically are not questions simply requiring right and wrong answers (e.g., 'yes' or 'no'), and teachers need to be patient to allow for student thinking before answering. Often, it is effective to have students share potential answers with each other. Short quizzes or other tasks, as well as interviewing with students, are also useful in obtaining evidence of student progress.

Once the evidence is gathered, feedback is given to students about their performance. There is much research on the nature of feedback that is effective in helping students learn (Brookhart, 2008). The timing and nature of the feedback needs to be appropriate, coming as soon as feasible after the performance and being specific and individualized. General evaluative statements such as 'good job' or 'correct' or 'excellent work' are not considered specific and individualized, and may in fact demotivate students. Rather, the information provided to the students must be directly tied to the criteria and their specific responses, and should be targeted to each student or small groups of students. The idea is to help the student see how their performance is making progress toward the learning target, in specific ways, and to help students understand that their lack of achievement is primarily due to lack of effort. Effort attributions are very important for the development of perseverance by helping students understand that success is more determined by what they do in the future than what has been done.

In general, effective feedback from information obtained from assessment has the following characteristics (McMillan, 2014):

- Focused on connecting evidence of learning to progress toward successful outcomes

- Positive without sugarcoating or effusive praise
- Honest and accurate
- Specific, individualized, and differentiated to students as appropriate
- Timely, typically immediately
- Descriptive of work accomplished, not about the student more generally
- Actionable, so students can take next steps
- Engaging so that students generate feedback
- Differentiated to produce the best motivation for each student
- Highlight student errors or omissions
- Focused to push students to next levels of learning
- Encourages a mastery rather than performance orientation toward learning

The final step in effective assessment *for* learning is to provide instructional adjustments or correctives. In this step the teacher helps students understand what else can be done to learn the material or deepen understanding. This typically means more learning activities that are different from what was done previously. Often students can come up with their own good ideas about what they can do to improve their understanding, which is excellent in promoting self-monitoring and self-determination.

The idea of assessment *for* learning is that it makes explicit the way assessments are designed and used to have a positive effect on student achievement and motivation. It is a philosophy of how curriculum, instruction, and assessment can be integrated to impact what students learn and their engagement in learning. It is especially helpful for the development of student dispositions needed for success in their careers and lives because it focuses on mastery of knowledge and skills, not simply performance for a good test score, and because it enhances students' abilities to evaluate their understanding of something, identify where the gap is between what they know and the target, and then design what further learning activities are needed to reach the achievement goals. It is also a frame of mind for teachers – how committed they are to improving student learning and motivation.

Characteristics of High-Quality Classroom Assessments

For classroom assessment to be successful in meeting its goals there are several indicators of quality that translate into effective practice. Classroom assessments that have high quality result in accurate, trustworthy verification of learning, appropriate motivation of students for learning, and helpful information to improve instruction. One characteristic already indicated is the determination of clear objectives and learning targets. It is best if these are understood by students and parents as well as teachers.

Alignment

Alignment is the degree to which different components of assessment that are essential to produce intended outcomes are in agreement, supportive, or consistent. There are several important ways that alignment needs to be demonstrated, beginning with the learning objectives or targets.

Assessment is most effective when it is aligned with a teacher's philosophy of education and style of instruction. Some teachers are formal in their approach to instruction, while others take a more facilitative, personal mode of interaction with students. It is important for teaching styles to be aligned with student learning styles, and to be aligned with learning targets and assessments. Teachers with a formal approach may tend to lecture and give traditional tests. Teachers with a more collaborative style include more discussion, project-based activities, cooperative learning, and assessments that are performance-based, authentic, and require students to apply their knowledge.

Classroom assessments need to be structured, administered, and scored in alignment with contemporary theories of human learning and motivation. The research in these areas has emphasized the critical role that students' existing knowledge plays in making connections between what is new information and what is currently understood. Learning is most effective when it is meaningful; motivation is most effective when it is mastery oriented and develops self-monitoring and self-efficacy in students (students' beliefs that they are capable of learning). Implications of these theories for assessment are clear for both instructions and assessment, calling for more authentic, performance-based, and project-based assessments rather than objective tests, more variety in assessment methods, more formative assessment, and more individualized feedback. Mastery goal setting is promoted by the use of clear targets and criteria for scoring assessments prior to testing, the use of exemplars, and student self-assessment. The goal is to maximize student engagement and meaningfulness in learning to establish effort attributions for both success and failure.

Another important type of alignment is between the nature of learning targets and type of assessment. Assessments can be categorized broadly into four major types: selected response, constructed response, teacher observation, and student self-assessment (McMillan, 2014). (Peer assessment could be listed as a fifth category, although it is not widely used.) Selected-response tests consist of multiple-choice, matching, true–false, short answers, and completion sections. Constructed-response assessments include performance, essay, and oral questioning. *Performance assessments* require students to construct an extensive, complex answer or response, often in the form of a presentation or something that is constructed or accomplished. The assessment is a product such as a speech, athletic demonstration, musical recital, or project. These types of assessments require the development of a meaningful task to complete and a scoring rubric that specifies different levels of performance with criteria. Teacher observation can be formal but is more often informal. *Student self-assessment*, or self-reflection, refers to students rating their own performance.

Different types of assessment are best at measuring certain kinds of learning objectives or targets. Well-constructed selected-response items are best at measuring subject matter and procedural knowledge and comprehension, especially when students need to recognize or remember facts, dates, people, historical events, spellings, and concepts. Deep understanding and reasoning is best assessed with essays and performance assessments. Products and performances are only well assessed with performance assessments. Teacher observation is effective in measuring student dispositions, such as attitudes,

cooperativeness, effort, trust, and responsibility. Student self-assessments are effective in gathering data on student dispositions and students' abilities to understand learning criteria, what progress has been made, and what else needs to be learned. This self-regulation process contributes to self-determination and a sense of self-control, which provides intrinsic motivation and stronger positive expectations for future learning.

Finally, classroom assessments need to be well aligned with state standards. This requires a thorough understanding of the levels of cognition required in state standards, the types of items in tests used to assess state standards, and how classroom assessment formats and procedures match these dimensions. A rough match can be made simply on the basis of content; a more sophisticated, refined match is achieved by understanding the depth, range, scope, and balance of knowledge and skills needed.

Validity

Validity is the extent to which the use of student assessments is appropriate. It is a measure of the reasonableness of the interpretations and inferences that are made from the results, as well as the consequences that follow. For example, if a conclusion is reached that a student's performance indicates that there is poor achievement, is that true? Or, if an assessment indicates that a student is proficient, what is the chance that is wrong? If a consequence of an assessment is that students learn only to study to pass the test and not to master the content, is that what is desired?

While for standardized tests technical approaches to establishing validity are well defined, validity for classroom assessments relies more on common sense, comparisons, logic, and careful examination of the nature of the assessments. This evidence is gathered by constructing a *test blueprint* or *table of specifications*. The blueprint is a matrix that shows the type of learning that is measured by different areas of the test. The number and percent of items covering different cognitive tasks in each area provides a picture to be sure that the content and levels of cognition required covers what is meant to be covered. This could be called *content-related evidence* for validity, and it is the most common type of evidence for classroom assessments. A related kind of evidence focuses on *instructional sensitivity* by comparing what is on the test with what was taught. Often both content-related evidence and instructional sensitivity are established by having others review the assessments in the context of what was taught during the instructional segment.

Another type of evidence for validity comes from several measures of the same thing when the results point toward the same conclusion. This occurs when the quiz, homework, test, and project grades on the same thing are similar, or when teachers' observations of understanding from questioning match how students perform on a unit test. It is best to use multiple measures of the objective or learning target if possible, ideally with different methods of measurement.

Reliability

All classroom assessments contain some degree of error or imprecision, some amount of 'noise' that interferes with an absolutely correct result. In measurement, the concept of *reliability* is used to define and estimate the amount of error that is contained in a single assessment. Reliability, then, is an indication of stability, consistency, or dependability of the scores that are obtained from an assessment. The less the error in the measure, the greater the reliability. The amount or degree of error in a classroom assessment, like validity, is usually a matter of professional judgment. Error can come from the nature of the assessment and scoring procedures, such as from ambiguous directions and poorly worded items, to biased or tired scorers. Error also comes from the student, with such factors as being overly tired or sick on the testing day, not being motivated to do the best work, anxiety, or how lucky the student was in answering questions. Usually teachers are not aware of how these sources of error affect results, so a general understanding of conditions and students is needed. A more reliable score is obtained when several questions are asked about the same thing. This occurs when a math test has several two-digit multiplication items to measure this skill. If all the items are answered correctly by one student who clearly knows how and incorrectly by a student who clearly does not know how, there is evidence that at least the test does not contain much error. However that does not address other sources of error, so even with the best of tests final scores should be interpreted with a margin of error, much like what is reported in political polling. That means that a score of 85% is more accurately something like 82–87% or 83–86%. The students' actual or 'true' knowledge or capability is something within the range. Assessment practices that can improve reliability include providing clear guidelines for answering and scoring, providing several items or tasks to measure the same thing, using independent raters or scorers if possible, keeping interruptions when students take a test to a minimum, using exemplar answers and papers for scoring, using specific scoring rubrics, and using shorter assessments more frequently rather than longer assessments less often.

Fairness

A *fair* assessment is one that provides all students, regardless of their characteristics and circumstances, a reasonable opportunity to demonstrate achievement. In this sense, fair assessments are unbiased and nondiscriminatory (Tierney, 2013). A *biased* assessment is influenced by factors that are not associated with the knowledge or skill to be demonstrated. This can result from biased assessment content that may unfairly penalize a student or be offensive due to culture, income, ethnicity, or gender (Popham, 2008). Unfair penalization occurs when some students, because of their status, experience, or characteristics, are at a disadvantage in taking the test. Conversely, some students may have an advantage. Suppose, for example, that a math test item uses a sailing example that makes it easier for those students who have sailed and more difficult for those who have never sailed. This would be a biased item. Cultural differences reflected in vocabulary, values, and conventions can unfairly influence the ability of some students to show what they know and can do. Even students' learning style preferences can influence the performance of some students on some types of assessments. Students can also be offended by culturally based, demeaning content in assessments, such as portraying a given race as having only low-status jobs. Finally, fairness is reflected in the extent to which appropriate

accommodations are included for students with special needs and English Language Learners.

Practicality and Efficiency

A continuing challenge to good teaching is to balance the potential complexity and extensiveness of many assessments with the need to be both practical and efficient. Teachers have limited time for assessment. The ideal is to use just enough assessment to reach valid conclusions and promote positive consequences for students (e.g., enhancing their motivation, self-reflection, and overall achievement). It is best to consider the time needed to construct, administer, and score assessments. Some constructed-response assessments may be great for promoting thinking skills, but there needs to be consideration of what will be required to do the scoring and give feedback. Objective tests are easily scored, although much time is needed to produce good multiple-choice questions, ones where one or two alternatives are not obviously incorrect. Other things being equal, it is best to use the shortest possible assessments, as long as they provide valid, reliable, and fair results.

Grading and Reporting

Grading (marking) and reporting are long-standing practices that are closely aligned to classroom assessment. The results of classroom assessments are used, sometimes exclusively, to determine grades. Grades are an indication of a student's achievement or performance (Brookhart, 2009). Marks or symbols are used to convey a message that has a predetermined meaning. Letter marks, from A to F, are used extensively in grading. It is also common to use percentage correct to correspond to each grade (e.g., 90–100% – A, 80–89% – B, and 70–79% – C), and often pluses and minuses are added to the letters when the scores are at the ends of each range of percentages. The grade is then labeled with a descriptor such as 'excellent,' 'good,' 'fair,' 'poor,' or 'failing.' Traditionally, letter grades are not distributed evenly to a group of students. That is, fewer students typically receive As, Ds, and Fs, and most students receive Bs or Cs, although the distribution can vary significantly from one class to another. This is often left to the option of the teacher. While teachers try to be 'objective' in their grading and use measures of academic achievement, some level of subjectivity and professional judgment is needed. Naturally, this can vary from one teacher to another, even for the same course or same group of students. Some teachers make hard tests, others easy tests. Many teachers use some form of extra credit, and improvement and effort is often used as part of what determines the grade. Grading essays, papers, and projects is essentially a matter of professional judgment. In the end, each teacher uses his or her experience and knowledge in constructing and grading classroom assessments. Grades in higher-level classes, such as honors and advanced placement classes, are often given higher points than are given in lower-level classes.

A more recent trend in grading is to focus on absolute levels of performance. This is called *standards-based* grading. Standards-based grading is very similar to what was called criterion-referenced grading in the sense that grades are based on preestablished levels of performance that are thoroughly and clearly described and understood. The standards are sometimes state standards, although typically teachers use descriptions of different levels of performance in classroom assessments as well. The levels are differentiated by using a rubric that includes descriptors to indicate increasingly more sophisticated understanding or skills. For example, the scale could begin with 'needs improvement,' progress to 'approaching,' then 'proficient,' and finally 'advanced.' The descriptors in the rubric vary considerably, but each has a definition to indicate in general what the student knows, understands, and is able to do.

With standards-based grading the basis of comparison is to examine student work and match it with the appropriate levels of performance. This is in contrast to what is called *norm-referenced* grading, in which the basis of comparison is how other students perform. In norm-referenced grading only the best achieving students, as compared to others, get the highest grades. This is a long-standing approach to grading and is still important for ranking students for such purposes as achieving honors, admittance to college, and employer evaluations.

A final and less frequent type of grading is *self-referenced*. The essence of self-referenced grading is to compare students' final performance after instruction to their performance in the past, or, less frequently, to their aptitude. The logic here is that what is most important is growth in performance, not simply the level of performance. Thus, students may initially have a very weak understanding and after instruction advance to an adequate or proficient level. This could indicate a significant and important amount of growth, and be graded highly. A student who begins at the proficient level but does not progress much would receive a lower grade. While measuring student progress is now critical to evaluating teachers and schools, it is not without disadvantages. Measuring growth with classroom assessments, or any kind of assessment for that matter, suggests a probable doubling of testing time, relies on having reliable measures, assumes appropriate student motivation when taking 'pretests,' and somehow getting 'aptitude' right if that factor is used as a premeasure.

Final semester or course grades are determined from classroom assessments as a summary indicator of student performance. Web-based and other software grading programs are used to combine grades, points, and percentages of all the assessments to result in a final score, which is then usually converted to a grade. Teachers combine the individual assessments, deciding how much weight each one should be given and whether scores are averaged or added (total points method). Exams are typically given more weight than are quizzes and homework. Both students and parents are usually able to see grades and final calculations online.

Along with reporting grades, teachers indicate to students and parents strengths, weaknesses, and areas that need further improvement. This is accomplished through parent–teacher and student–teacher conferences, and/or in writing (Stiggins, 2008). In some instances, the student takes leadership for the conference, taking parents through a detailed review of their work for the grading period. Often this includes a portfolio of student products. The portfolio, which can be in a paper or electronic file, will contain periodic examples of student performance, such as tests, papers, and quizzes, along with student reflections of the meaning of the results. This type of student self-assessment is one of the most recent developments in classroom assessment, along with peer assessment. Both of these approaches are well

aligned with contemporary theories of motivation and learning, and will probably be commonplace in the future.

Summary

Classroom assessment is something all teachers do as part of their responsibility for enhancing student learning and motivation, documenting student performance, and reporting results for accountability purposes. There are many different types of classroom assessments that can be used, each with advantages and disadvantages. To the extent that teachers base their assessments on known indicators of high quality, such as reliability and validity, align their assessments with clear and appropriate learning objectives and targets, use formative assessment with meaningful feedback, and grade student work to provide meaningful summary indications of performance, student learning and motivation will be enhanced, as well as documented.

Abstract

This article reviews four decades of research on classroom climate, with a major thrust on the development, validity, and use of several frequently used and extensively validated questionnaires. Another purpose is to review several lines of past classroom climate research, including evaluation of educational innovations, associations between student outcomes and classroom climate, and teachers' action research attempts to improve their classroom climates.

Over 40 years ago, Herbert Walberg and Rudolf Moos began seminal independent programs of research which form the starting points for the work reviewed in this article. Walberg developed the Learning Environment Inventory (LEI) as part of the research and evaluation activities of Harvard Project Physics (Walberg and Anderson, 1968), whereas Moos developed numerous social climate scales, including those for use in psychiatric hospitals and correctional institutions, which ultimately led to the development of the Classroom Environment Scale (CES; Trickett and Moos, 1973). Walberg's and Moos' work built upon Lewin's (1936) seminal field theory, which recognized that both the environment and its interaction with personal characteristics of the individual are potent determinants of human behavior, and Murray's (1938) needs-press model, which allows the analogous representation of person and environment in common terms. The way in which this important pioneering work on perceptions of classroom climate spawned other research is reflected in books (Fisher and Khine, 2006; Fraser, 1986; Fraser and Walberg, 1991), literature reviews (Fraser, 2007), the American Educational Research Association's Special Interest Group on Learning Environments which began in the mid-1980s, the initiation in 1998 of Kluwer/Springer's *Learning Environments Research: An International Journal*, and the birth in 2008 of Sense Publishers' book series *Advances in Learning Environments Research* (Aldridge and Fraser, 2008).

Following the pioneering research of Walberg and Moos in the USA, two further programs of learning environments research emerged. In the Netherlands, Theo Wubbels and his colleagues began ambitious programmatic research focusing specifically on the interactions between teachers and students in the classroom and often involving use of the Questionnaire on Teacher Interaction (QTI). This research program is described in more detail below. In Australia, Barry Fraser and his colleagues began programmatic research, which first focused on student-centered classrooms and involved use of the Individualized Classroom Environment Questionnaire (ICEQ; Fraser, 1990). The ICEQ differs from the LEI and CES, which focus on teacher-centered classrooms, in that it assesses those dimensions that are salient in open or individualized classroom settings. Subsequently, this led to other specific-purpose classroom climate instruments in Australia and cross-validating and applying them for a variety of research purposes around the world, as discussed in detail later in this article.

Instruments for Assessing Classroom Climate

Historically Significant Questionnaires: LEI, CES, ICEQ, and MCI

As noted above, the LEI, CES, and ICEQ were important in the evolution of the field of classroom climate even though they are seldom used in contemporary educational research. On the other hand, the My Class Inventory (MCI) – a simplified version of the LEI for younger students – is still used to some extent today because of its particularly low reading level.

Fraser et al.'s (1982) version of the MCI was developed for use among children aged 8–12 years, but subsequently Fisher and Fraser (1981) simplified the original version of the MCI and later Fraser and O'Brien (1985) evolved and used a short 25-item version. Although the MCI was developed originally for use at the primary school level, it has also been found to be very useful with students in the junior high school, especially with those who might experience reading difficulties with other instruments. The MCI contains only five of the LEI's original 15 scales, item wording has been simplified to enhance readability, the LEI's four-point response format has been reduced to a two-point (Yes–No) response format, and students answer on the questionnaire itself instead of on a separate response sheet to avoid errors in transferring responses from one place to another.

Goh and Fraser (1998) modified the MCI to involve a three-point frequency response format (Seldom, Sometimes, and Most of the Time) and a Task Orientation scale, and they used it in research in Singapore among primary mathematics students. In Brunei Darussalam, Majeed et al. (2002) used an English-language version of the MCI among 1565 lower-secondary mathematics students in 81 classes in 15 government schools and reported sex differences in classroom climate perceptions and associations between students' satisfaction and the classroom environment. In a small-scale evaluation of a K-5 program that integrates mathematics and children's literature, Mink and Fraser (2005) used the MCI in Florida and found congruence between students' actual and preferred classroom climate. In Texas, Scott Houston et al. (2008) used the MCI in an evaluation of science kits among a sample of 588 grade 3–5 students. As well as attesting to the validity of the MCI, using science kits was associated with a more positive classroom climate in terms of student satisfaction and cohesiveness. Sink and Spencer (2005) advocate the use of the MCI as an accountability tool for elementary-school counsellors. Using a large sample of 2835 grade 4–6 students in an

urban school district in Washington State, these researchers found that an 18-item revision of the MCI was psychometrically sound. Implications for elementary-school counseling programs and practices and their evaluation were provided by the authors.

Questionnaire on Teacher Interaction

As noted above, pioneering and programmatic research which originated in The Netherlands focuses on the nature and quality of interpersonal relationships between teachers and students (Wubbels and Brekelmans, 2012). Drawing upon a theoretical model of proximity (cooperation–opposition) and influence (dominance–submission), the QTI was developed to assess student perceptions of eight behavior aspects. Each item has a five-point response scale ranging from Never to Always.

Although research with the QTI began at the senior high school level in The Netherlands, cross-validation and comparative work has been completed at various grade levels in the USA (Wubbels and Levy, 1993) and Australia (Fisher et al., 1995) and a more economical 48-item version has been developed and validated in Singapore (Goh and Fraser, 1996). In Brunei Darussalam, Scott and Fisher (2004) validated a version of the QTI in Standard Malay with 3104 students in 136 elementary-school classrooms and showed that achievement was related positively to cooperative behaviors and negatively to submissive behaviors. In Singapore, Quek et al. (2005) validated an English version of the QTI with 497 gifted and non-gifted secondary school chemistry students and reported some stream (i.e., gifted and non-gifted) and sex differences in QTI scores. In Korea, a translated version of the QTI was validated and used by Lee et al. (2003) among 439 science students and by Kim et al. (2000) among 543 students. In Indonesia, a translated version of the QTI was validated with a sample of 422 university students by Fraser et al. (2010b). Brekelmans et al. (2005) traced changes in teacher–student relationships across the teaching career for samples from various countries.

Constructivist Learning Environment Survey

Taylor et al. (1997) developed the Constructivist Learning Environment Survey (CLES) to assist researchers and teachers to assess the degree to which a particular classroom's climate is consistent with a constructivist epistemology, and to assist teachers to reflect on their epistemological assumptions and reshape their teaching practices. Taylor and his colleagues reported sound factorial validity and internal consistency reliability for the CLES for several diverse samples.

Working with 1079 students in 59 science classes in North Texas, Nix et al. (2005) reported strong support for the validity of the CLES. An evaluation of an innovative science teacher professional development program revealed that the students of these teachers perceived their classrooms more favorably than did the students of other teachers. In a follow-up study in Texas, Nix and Fraser (2010) used a shorter version of the CLES in an evaluation of the implementation of the same professional development model over three semesters involving 17 teachers and 845 students. Changing teachers' classroom climate at the university level was found to foster similar changes in their students' middle-school classroom climates.

In a cross-national study of junior high school science classroom climates, the English version of the CLES was administered to 1081 students in 50 classes in Australia while a Mandarin translation was administered to 1879 students in 50 classes in Taiwan. Aldridge et al. (2000) reported sound validity for both English and Mandarin versions, and also that Australian classes were perceived as being more constructivist than Taiwanese classes (especially in terms of Critical Voice and Student Negotiation).

Peiro and Fraser (2009) modified the CLES, translated it into Spanish, and administered the English and Spanish versions to 739 grade K-3 science students in Miami, USA. Analyses supported the validity of the modified English and Spanish versions when used with these young children. Strong and positive associations were found between students' attitudes and the nature of the classroom climate, and a 3-month classroom intervention led to large and educationally important changes in classroom environment.

In South Africa, Aldridge et al. (2004b) administered the English version of the CLES to 1864 grade 4–6 mathematics learners in 43 classes. This led to the cross-validation of this version of the CLES for this population in terms of factorial validity, internal consistency, reliability, and ability to differentiate between classrooms. The primary focus of this study was to assist South African teachers to become more reflective practitioners in their daily classroom teaching. Through the use of the CLES in teacher action research, some improvements in the constructivist orientation of classrooms were achieved during a 12-week intervention.

When Kim et al. (1999) translated the CLES into the Korean language and cross-validated it with a sample of 1083 students in 24 grade 10 science students, results supported the factor structure and reliability of the Korean version, revealed statistically significant relationships between classroom climate and students' attitudes to science, and confirmed that students exposed to a new curriculum perceived a more constructivist learning environment than did students who had not been exposed to this curriculum.

Science Laboratory Environment Inventory

Because of the critical importance and uniqueness of laboratory settings in science education, an instrument specifically suited to assessing the climate of science laboratory classes at the senior high school or higher education levels was developed (Fraser et al., 1995; Fraser and McRobbie, 1995; Fraser et al., 1993). The Science Laboratory Environment Inventory (SLEI) has five scales (each with seven items) and the five frequency response alternatives are Almost Never, Seldom, Sometimes, Often, and Very Often. The SLEI was field tested and originally validated simultaneously with a sample of over 5447 students in 269 classes in six different countries (USA, Canada, England, Israel, Australia, and Nigeria). Subsequently, it was cross-validated in Australia with 1594 students in 92 classes by Fraser and McRobbie (1995) and 489 senior high school biology students by Fisher et al. (1997).

Fraser and Lee (2009) translated the SLEI into the Korean language in a study of differences between the classroom

climates of three streams (science-independent, science-oriented, and humanities) among a sample of 439 high school students. The Korean version of the SLEI exhibited sound factorial validity and internal consistency reliability, and was able to differentiate between the perceptions of students in different classes. Generally, students in the science-independent stream perceived their laboratory classroom climates more favorably than did students in either of the other two streams. Working with a sample of 761 high school biology students in 25 classes in southeastern USA, Lightburn and Fraser (2007) used the SLEI in an evaluation of the effectiveness of using anthropometry activities. Data analyses supported not only the SLEI's validity (in terms of factor structure, internal consistency reliability, and ability to differentiate between classrooms), but also suggested that there was a positive influence of using anthropometric activities in terms of both classroom climate and student attitudes.

WIHIC Questionnaire

According to Dorman (2008, p. 181), "the WIHIC has achieved almost bandwagon status in the assessment of classroom environments." The What Is Happening In This Class? (WIHIC) combines modified versions of the most salient scales from a wide range of existing questionnaires with additional scales that accommodate contemporary educational concerns (e.g., equity and constructivism). Also, the WIHIC has a separate Class form (which assesses a student's perceptions of the class as a whole) and Personal form (which assesses a student's personal perceptions of his or her role in a classroom).

Developed by Fraser et al. (1996), the original 90-item nine-scale version was refined by both statistical analysis of data from 355 junior high school science students, and extensive interviewing of students about their views of their classroom environments in general, the wording and salience of individual items, and their questionnaire responses. The field testing of a second version of the WIHIC involved junior high school science classes in Australia and Taiwan. While the Australian sample of 1081 students in 50 classes responded to the original English version, a Taiwanese sample of 1879 students in 50 classes responded to a Chinese version that had undergone careful procedures of translation and back translation (Aldridge et al., 1999). For both the Australian and Taiwanese samples, strong factorial validity and internal consistency reliability were reported.

A comprehensive validation of the WIHIC was conducted by Dorman (2003) using a cross-national sample of 3980 high school students from Australia, the UK, and Canada. Confirmatory factor analysis supported the seven-scale a priori structure, with fit statistics indicating a good fit of the model to the data. The use of multisample analyses within structural equation modeling substantiated invariant factor structures for the three grouping variables of country, grade level, and student sex. In a second study, Dorman (2008) used both the actual and preferred forms of the WIHIC with a sample of 978 secondary school students from Australia. Separate confirmatory factor analyses for the actual and preferred forms supported the seven-scale a priori structure, with fit statistics again indicating a good fit of the models to the data. The use of multitrait–multimethod modeling with the seven scales as traits and the two forms of the instrument as methods supported the WIHIC's construct validity.

The WIHIC has been used in various countries and in various languages. Cross-national research was conducted in Australia, the UK, and Canada in English by Dorman (2003), in Australia and Indonesia in two languages by Fraser et al. (2010a), and in Australia and Canada by Zandvliet and Fraser (2005). The WIHIC was used in English in Singapore by Chionh and Fraser (2009) and Khoo and Fraser (2008), in India by Koul and Fisher (2005), in Australia by Dorman (2008), and in South Africa by Aldridge et al. (2009). Other researchers used the WIHIC, respectively, in the Korean language in Korea (Kim et al., 2000) and in the Indonesian language in Indonesia (Wahyudi and Treagust, 2004). Other studies involved the use of an Arabic translation of the WIHIC in the UAE (Afari et al., 2013; MacLeod and Fraser, 2010).

Research that involved the use of the WIHIC in the USA includes three studies in California by den Brok et al. (2006b), Martin-Dunlop and Fraser (2008), and Ogbuehi and Fraser (2007); a study in New York by Wolf and Fraser (2008); and studies in Florida by Pickett and Fraser (2009), Allen and Fraser (2007), Robinson and Fraser (2013), and Helding and Fraser (2013). Although all the four studies in Florida involved the use of an English-language version of the WIHIC, it is noteworthy that three of them offered students the option of responding to a version of the WIHIC in either Spanish or in English.

Instruments Based on WIHIC: OBLEQ, TROFLEI, and COLES

Numerous researchers have incorporated WIHIC scales into specific-purpose questionnaires tailored to particular contexts and purposes. For example, working with a sample of 2638 grade 8 science students from 50 classes in 50 schools in the Limpopo Province of South Africa, Aldridge et al. (2006) developed and validated the Outcomes-Based Learning Environment Questionnaire (OBLEQ) in the Sepedi language for monitoring the implementation of outcomes-based classroom climates. As well as validating a widely applicable questionnaire suited for outcomes-based education, the researchers used case studies to support and check the accuracy of profiles of OBLEQ scores for specific classes.

Outcomes-focused education is an approach to school reform in which planning, delivery, and assessment all focus on the student's outcomes/results from teaching rather than on a syllabus or curriculum. Aldridge and Fraser (2008) conducted a study of an innovative new postsecondary school, whose emphases included an outcomes focus and the use of ICT in program delivery, during its first year of operation. As part of the formative and summative evaluations of this new school, they designed and used the Technology-Rich Outcomes-Focused Learning Environment Inventory (TROFLEI), which not only incorporates all of the WIHIC's seven scales, but also includes three other important scales that were salient in the context of this new school: Differentiation, Computer Usage, and Young Adult Ethos. The TROFLEI has eight items in each of the eight scales that are responded to using a five-point frequency scale (Almost Never, Seldom, Sometimes, Often, and Almost Always). An innovative aspect of the TROFLEI is that it employs a side-by-side response

format which enables students to provide their separate perceptions of actual and preferred classroom climate in an economical way.

Using a large sample of 2317 students from 166 grade 11 and 12 classes from Western Australia and Tasmania, Aldridge and Fraser (2008) reported strong factorial validity and internal consistency reliability for both the actual and preferred forms of the TROFLEI. Aldridge et al. (2004a) used multitrait–multimethod modeling with a subsample of 1249 students, of whom 772 were from Western Australia and 477 were from Tasmania (compared with 2317 students in our entire sample). When the 10 TROFLEI scales were used as traits and the actual and preferred forms of the instrument as methods, the results supported the TROFLEI's construct validity and sound psychometric properties, as well as indicating that the actual and preferred forms share a common structure.

When the TROFLEI was used in monitoring and evaluating the success of the new school in promoting outcomes-focused education, changes in students' perceptions of their classroom climates over four years supported the efficacy of the school's educational programs (Aldridge and Fraser, 2008). Using structural equation modeling with a sample of 4146 grade 8–13 students, Dorman and Fraser (2009) used the TROFLEI to establish associations between students' affective outcomes and their classroom climate perceptions. In an investigation of some determinants of classroom climate involving the use of TROFLEI with 2317 students, Aldridge and Fraser (2008) reported interesting differences in classroom climate perceptions between male and female students and between students enrolled in university-entrance examinations and in wholly school-assessed subjects. With the sample of 4146 students, Dorman et al. (2006) used cluster analysis with TROFLEI responses to identify five relatively homogeneous groups of classroom environments.

The Constructivist-Orientated Learning Environment Survey (COLES) incorporates numerous scales from the WIHIC into an instrument that is designed to provide feedback as a basis for reflection in teacher action research. In constructing the COLES, Aldridge et al. (2012) were especially conscious of the omission in all existing classroom environment questionnaires of important aspects related to the assessment of student learning. The COLES incorporates six of the WIHIC's seven scales (namely Student Cohesiveness, Teacher Support, Involvement, Task Orientation, Cooperation, and Equity). Like the TROFLEI, the COLES also includes the scales of Differentiation and Young Adult Ethos. In addition, the COLES includes the Personal Relevance scale from the CLES (the extent to which learning activities are relevant to the student's everyday out-of-school experiences). The two new COLES scales related to assessment are Formative Assessment (the extent to which students feel that the assessment tasks given to them make a positive contribution to their learning) and Assessment Criteria (the extent to which assessment criteria are explicit so that the basis for judgments is clear and public).

For a sample of 2043 grade 11 and 12 students from 147 classes in 9 schools in Western Australia, data analyses supported the sound factorial validity and internal consistency reliability of both actual and preferred versions of the COLES. A noteworthy methodological feature of this study was that the Rasch model was used to convert data collected using a frequency response scale into interval data suitable for parametric analyses. Interestingly, when analyses were performed separately for raw scores and Rasch scores, Aldridge et al. (2012) found that the differences between the validity results (e.g., reliability, discriminant validity, and ability to differentiate between classrooms) were negligible. During action research with teachers, feedback based on students' responses to both the actual and preferred versions of the COLES was used, in conjunction with reflective journals, written feedback, discussion at a forum, and teacher interviews. Aldridge et al. (2012) reported the experiences of these teachers concerning the viability of using feedback from the COLES as part of their action research aimed at improving their classroom climates.

Research Involving Educational Environment Instruments

The main types of past research considered in this section are (1) use of climate dimensions as criterion variables in the evaluation of educational innovations, (2) associations between student outcomes and classroom climate, (3) teachers' practical attempts to improve their classroom and school environments, and (4) other types of research with classroom climate instruments.

Evaluation of Educational Innovations

Classroom climate instruments can be useful as a source of process criteria in the evaluation of educational innovations. For example, by incorporating a classroom climate instrument within an evaluation of the use of a computerized database, Maor and Fraser (1996) found that students perceived that their classes became more inquiry oriented during the use of the innovation. In two studies in Singapore, classroom climate measures were used as dependent variables in evaluations of computer-assisted learning by Teh and Fraser (1994) and computer application courses for adults by Khoo and Fraser (2008).

Nix et al. (2005) used the CLES in their evaluation of an innovative science teacher development program. Programs were evaluated in terms of the types of school classroom climates created by these teachers as perceived by their 445 students in 25 classes. Students provided their perceptions of THIS classroom (the students' current class with the teacher who had experienced the professional development) and OTHER classroom (other classes at the same school taught by different teachers). Students of teachers who had experienced the professional development perceived their classrooms as having appreciably higher levels of the scales of Personal Relevance and Uncertainty relative to the comparison classes.

Martin-Dunlop and Fraser (2008) evaluated an innovative science course for prospective elementary teachers in a large urban university in California. When classroom climate scales selected from the WIHIC and SLEI were administered to 525 females in 27 classes, very large differences were found on all scales (over 1.5 standard deviations) between students' perceptions of the innovative course and that of their previous courses.

In a study of 761 high school biology students in southeastern USA, Lightburn and Fraser (2007) used the SLEI in an

evaluation of the effectiveness of using anthropometric activities. Relative to a comparison group, the anthropometry group had significantly higher scores on some SLEI and attitude scales.

Pickett and Fraser (2009) argued that the litmus test of the success of any teacher professional development program is the extent of changes in teaching behaviors and ultimately student outcomes in the participating teachers' school classrooms. Consequently, their evaluation of a two-year mentoring program in science for beginning elementary-school teachers drew on the field of classroom climate in gauging this program's success in terms of participants' classroom teaching behavior as assessed by their school students' perceptions of their classroom climates. The efficacy of the mentoring program was supported in terms of some improvements over time in the classroom climate.

In New York, Wolf and Fraser evaluated the effectiveness of using inquiry-based laboratory activities in terms of classroom climate, attitudes, and achievement. Administration of the WIHIC to 1434 middle-school science students in 71 classes supported the validity of the WIHIC and analyses for a subsample of students revealed that inquiry instruction promoted more Student Cohesiveness than did non-inquiry instruction (effect size of one-third of a standard deviation). As well inquiry-based instruction was differentially effective for male and female students.

Associations between Student Outcomes and Climate

Numerous research programs have shown that student perceptions account for appreciable amounts of variance in learning outcomes, often beyond that attributable to background student characteristics. For example, using the SLEI, associations with students' cognitive and affective outcomes have been established for a sample of approximately 80 senior high school chemistry classes in Australia (Fraser and McRobbie, 1995; McRobbie and Fraser, 1993), 489 senior high school biology students in Australia (Fisher et al., 1997), and 1592 grade 10 chemistry students in Singapore (Wong and Fraser, 1996). Using the QTI, associations between student outcomes and perceived patterns of teacher–student interaction were reported for samples of 489 senior high school biology students in Australia (Fisher et al., 1995), 1512 primary school mathematics students in Singapore (Goh et al., 1995), and 7484 grade 9 to 11 students from 278 classes in 55 public schools in 13 major Turkish cities (Telli et al., 2010).

While many past learning environment studies have employed techniques such as multiple regression analysis, few have used the multilevel analysis in order to take cognizance of the hierarchical nature of classroom settings (den Brok et al., 2006a). Two studies of outcome–environment associations compared the results obtained from multiple regression analysis with those obtained from an analysis involving the hierarchical linear model. In Wong et al.'s (1997) study involving 1592 grade 10 students in 56 chemistry classes in Singapore, associations were investigated between three student attitude measures and a modified version of the SLEI. In Goh et al.'s (1995) study with 1512 grade 5 mathematics students in 39 classes in Singapore, scores on a modified version of the MCI were related to student achievement and attitude. Most of the significant results from the multiple regression analyses were replicated in the HLM analyses, as well as being consistent in direction.

Dorman and Fraser (2009) investigated classroom climate, antecedent variables (gender, grade level, and home computer and Internet access), and student affective outcomes using the TROFLEI among 4146 high school students from Western Australia and Tasmania. The student outcome measures were attitude to the subject, attitude to computer use, and academic efficacy. Confirmatory factor analysis using LISREL supported the 10-scale a priori structure of the TROFLEI. When structural equation modeling using LISREL was used to test a postulated model involving antecedent variables, classroom environment and outcomes: improving classroom climate had the potential to improve student outcomes; antecedents did not have any significant direct effect on outcomes; and academic efficacy mediated the effect of several classroom climate dimensions on attitude to subject and attitude to computer use.

Teachers' Attempts to Improve Classroom Climate

Although much research has been conducted on educational climate, less has been done to help teachers to improve the climates of their own classrooms. Fraser and Fisher (1986) proposed five steps (assessment, feedback, reflection and discussion, intervention, and reassessment) for change attempts.

Yarrow et al. (1997) introduced 117 pre-service education teachers to the field of classroom climate through being involved in action research aimed at improving their university teacher education classes and their 117 primary school classes during teaching practice. Improvements in classroom climate were observed, and the pre-service teachers generally valued both the inclusion of the topic of classroom climate in their pre-service programs and the opportunity to be involved in action research aimed at improving classroom climates.

Two studies in South Africa employed this approach with teachers who used action research in an attempt to improve their classroom climates. In Aldridge et al.'s (2009) study, 31 in-service teachers undertaking a distance-education program administered a primary school version of the WIHIC in the Isi-Zulu language to 1077 grade 4–7 learners in the KwaZulu-Natal province. Different teachers were able to use feedback from the WIHIC with varying degrees of success in their attempts to improve their classroom climates. In Aldridge et al.'s (2004b) study, a group of 29 mathematics teachers administered the English version of the CLES to 1864 grade 4–9 learners in 43 classes. During an intervention phase in this study, some teachers were able to increase the constructivist orientation of their classrooms, thus supporting the efficacy of using the CLES to provide feedback to guide change.

Using the COLES, Aldridge et al. (2012) explored the viability of teachers using feedback based on their students' actual and preferred classroom climate perceptions for reflection in action research aimed at improving their classrooms. Reflective journals, written feedback, forum discussions, and teacher interviews also were used to provide feedback. Both actual and preferred forms of the COLES were administered on two occasions – first as a pretest prior to commencing the action research and as a posttest six weeks later after the implementation of classroom strategies aimed at reducing

actual–preferred discrepancies on selected COLES scales. Overall, teachers involved found that feedback information based on students' responses to the COLES prompted valuable reflection that led to implementing classroom changes that resulted in improvements in their classroom climate. An interesting feature of Aldridge et al.'s (2012) study was the use of the circular profiles as a means of providing each teacher with a comparison of mean actual and preferred responses to the COLES for his/her class.

Other Applications

Differences between students and teachers in their perceptions of the same actual classroom climate and of differences between the actual climate and that preferred by students or teachers were investigated by Fisher and Fraser (1983). Students preferred a more positive classroom climate than was actually present for all five ICEQ dimensions and teachers perceived a more positive classroom climate than did their students in the same classrooms on four of the ICEQ's dimensions.

Using both actual and preferred forms of educational climate instruments permits exploration of whether students achieve better when there is a higher similarity between the actual classroom climate and that preferred by students. Using a person–environment interaction framework, Fraser and Fisher (1983) reported that actual–preferred congruence (or person–environment fit) could be as important as the classroom climate per se in predicting student achievement of important affective and cognitive aims. The practical implication of these findings is that class achievement of certain outcomes might be enhanced by attempting to change the actual classroom climate in ways which make it more congruent with that preferred by the class.

Although most studies of educational climate have tended to focus on a single environment, there is potential in simultaneously considering the links between, and the joint influence of, two or more environments. In South Africa, Aldridge et al. (2011) used a school climate instrument with 50 secondary school science teachers from 50 different schools, together with a classroom climate questionnaire based on the WIHIC with the 2638 grade 8 students in the 50 classes of these 50 teachers. Although there emerged a small number of interesting specific relationships, overall, the school climate did not have a strong influence on what happens in classrooms. When Dorman et al. (1997) administered a classroom climate instrument to 2211 students in 104 classes and a school climate instrument to the 208 teachers of these classes, only weak associations between classroom climate and school climate were found. Although school rhetoric often would suggest that the school ethos would be transmitted to the classroom level, it appears that classrooms are somewhat insulated from the school as a whole.

Using secondary analysis of a large database from a Statewide Systemic Initiative in the USA, Fraser and Kahle (2007) examined the effects of several types of environments on student outcomes. Over three years, nearly 7000 students in 392 middle-school science and mathematics classes in 200 different schools responded to a questionnaire that assesses class, home, and peer environments as well as student attitudes. Students also completed an achievement measure. Rasch analyses allowed comparison across student cohorts and across schools. Findings confirmed the importance of extending research on classroom climates to include the learning climates of the home and the peer group. Although all three environments accounted for statistically significant amounts of unique variance in student attitudes, only the class climate (defined in terms of the frequency of use of standards-based teaching practices) accounted for statistically significant amounts of unique variance in student achievement scores.

The creation and empirical investigation of typologies of classroom climates has been pursued in only a handful of past studies. Working in Turkey with a Turkish translation of the WIHIC den Brok et al. (2010) created classroom climate profiles for a sample of 1474 high school biology students in 52 classes. The six distinct classroom profiles that emerged were self-directed learning; task-orientated cooperative learning; mainstream; task-orientated individualized; low-effective learning; and high-effective learning. The most common profile was the mainstream classroom for which all WIHIC scales had medium–high scores. Based on a sample of 4146 Australian students from 286 grade 8–13 classes, Dorman et al. (2006) used the 10-scale TROFLEI to develop a classroom typology. The five relatively homogeneous groups of classes that emerged were exemplary; safe and conservative; non-technological teacher centered; contested technological; and contested non-technological.

Classroom Level in Educational Effectiveness Research

Christopher A Hafen and Erik A Ruzek, University of Virginia, Charlottesville, VA, USA

Abstract

Valid measurement of effective classrooms requires a developmental approach to conceptualizing classroom processes. This article presents several theoretical models (e.g., teaching through interactions framework; connective instruction), which emphasize the importance of teacher–student interactions as a central driver for student learning and socioemotional development. Included in this discussion is research detailing how effective classrooms have teachers that engage students in developmentally appropriate ways, and what practices increase student engagement. The article ends with some discussion of professional development practices that might increase teacher effectiveness.

Understanding and describing an effective classroom across prekindergarten (pre-K) to grade 12 environments is challenging. How does one equate a high-quality classroom in kindergarten with a high-quality classroom in 10th grade? The answer, in part, comes from designating the classroom as a context, and placing the term 'effectiveness' in a broader developmental arena. In other words, what makes teachers effective, regardless of the grade level they teach, is the extent to which they offer opportunities for developmentally appropriate interactions for their students. This approach is strongly supported by decades of research on the power and importance of daily interactions as a driving force of child and adolescent growth and development (Bronfenbrenner and Morris, 1998). This point is oftentimes lost in the current educational setting, which rewards or punishes teachers and schools on the basis of student test scores, without considering the broader impact of a truly effective teacher. This article will discuss recent research on educational effectiveness with a particular focus on how developmentally appropriate interactions are pivotal for optimal student development.

Understanding the Goal of an Effective Classroom

While there is much debate on the degree to which standardized test scores and achievement data should be used for tracking student learning, there is little debate that the purpose of school is to aid in the social and intellectual learning of developing children and adolescents. That suggests that at any model for understanding an effective classroom should have as its foundation student engagement (Ames, 1992; Shernoff et al., 2003). Student engagement is the vehicle through which rich content is learned, positive developmental lessons take root, and general learning occurs. In other words, all roads toward an effective classroom travel through student engagement.

Focusing on whether or not a classroom is engaging to students should make understanding an effective classroom pretty straightforward. That is, if it were straightforward to measure and make sense of student engagement. However, there is much debate among researchers on how best to capture student engagement, as it is a multifaceted construct with behavioral, emotional, and persistence oriented markers (see Appleton et al., 2008 for review). Ultimately, what matters most for social and intellectual learning is the behavior a student endorses by either reporting that they are involved in classwork and engaged in a class or by actually physically demonstrating engagement. The specific interactions in a classroom that lead individual students to maintain engagement may differ (see Cooper, 2014 for illustrative examples), but in an effective classroom there needs to be clear and consistent evidence of engagement across the majority of students.

Assuming that student engagement is the key to an effective classroom leads to an obvious question, how does a teacher foster student engagement in the classroom? The answer may come in the form of the interactions a classroom provides. At the start of a school year, there are a wide range of student perceptions, abilities, and past experiences presenting a challenge to any teacher. Due to this variability, no single classroom approach will engage every student for every minute throughout the year. However, there are strong theoretical arguments that the most successful approaches focus efforts on connecting students emotionally and instructionally to the teacher, the content, and each other. This process has recently been coined connective instruction (Martin and Dowson, 2009).

One approach to studying connective instruction is provided by the Teaching through Interactions framework, which defines an effective classroom through the quality of three broad domains of interactions that students experience in the classroom (see **Table 1**). These domains include emotional, organizational, and instructional interactions. This structure is powerful as it allows stakeholders (researchers, educators, and parents) to use the same language to understand and discuss classroom quality, whether the classroom contains elementary-aged children or older students in middle or high school classrooms. For example, the Emotional Support domain of the framework includes the dimensions of Positive Climate, Teacher Sensitivity, and Regard for Student Perspectives. In a kindergarten classroom having high-quality Regard for Student Perspectives might involve creating more opportunities for students to move freely around the classroom, while having high quality Regard for Student Perspectives in a 10th grade classroom might entail creating opportunities for autonomy and leadership. Importantly, research on the

Table 1 Description of teaching through interactions framework

Domain	*Dimension*	*Description*
Emotional support	Positive climate	Reflects the emotional connection and relationships among teachers and students, and the warmth, respect, and enjoyment in verbal and nonverbal interactions.
	Negative climate	Reflects the level and intensity of expressed negativity among teachers and students in the classroom.
	Teacher sensitivity	Encompasses the teacher's awareness and responsiveness to the academic, social-emotional, and developmental needs of individual students and the entire class.
	Regard for student perspectives	Focuses on the extent to which the teacher is able to meet and capitalize on the social and developmental needs of adolescents by providing opportunities for student autonomy and leadership. Also considered are the extent to which student ideas and opinions are valued and content is made useful and relevant to adolescents.
Classroom organization	Behavior management	Encompasses the teacher's use of clear behavioral expectations and effective methods to prevent and redirect misbehavior.
	Productivity	Considers how well the teacher manages time and routines so that instructional time is maximized.
	Instructional learning formats	Focuses on the ways in which the teacher maximizes students' interest and engagement in learning. This includes teachers' use of interesting and engaging lessons and materials, active facilitation, and clarity of learning objectives.
Instructional support	Content understanding	Refers to both depth of the lesson content and the approaches used to help students comprehend the framework, key ideas, and procedures in an academic discipline. At a high level, this refers to interactions among the teacher and students that lead to an integrated understanding of facts, skills, concepts, and principles.
	Analysis and inquiry	Assesses the degree to which the teacher facilitates students' use of higher-level thinking skills, such as analysis, problem solving, reasoning, and creation through the application of knowledge and skills. Opportunities for demonstrating metacognition, i.e., thinking about thinking, are also included.
	Quality of feedback	Assesses the degree to which feedback expands and extends learning and understanding and encourages student participation. (At the secondary level, significant feedback may be provided by peers.)
	Instructional dialogue	Captures the purposeful use of dialogue-structured, cumulative questioning and discussion which guide and prompt students to facilitate students' understanding of content and language development. The extent to which these dialogues are distributed across all students in the class and across the class period is important to this rating.

Teaching through Interactions framework has yielded evidence for the consistency and utility of the framework across levels of the education system (Hamre et al., 2013; Hafen et al., in press).

This still leaves the question of what do effective teachers do that allows them to engage students? In the emotional domain, effective teachers demonstrate trust, respect, and warmth toward their students, along with a promotion of a sense of belonging by showing a genuine interest in students' lives. This creates an atmosphere in the classroom such that students see their teacher as willing to help, fair, knowledgeable, and easy to approach when issues arise socially or emotionally. In the organizational domain, effective teachers manage behavior proactively and maximize learning time by utilizing clear routines and quick transitions. This creates an atmosphere in the classroom where students take ownership and share control of the classroom. In the instructional domain, effective teachers provide clear learning targets, incorporate variety and novelty into their instruction, provide relevant and varied examples, encourage metacognitive processes, and provide timely feedback to scaffold student learning. This creates an atmosphere in the classroom in which students engage in higher-order thinking using novel concepts, yet feel comfortable asking questions and voicing their thought processes when learning new content. These processes can be studied at multiple levels (teacher, observer, student), each with its own insight toward understanding classroom effectiveness.

Understanding the Classroom from a Teacher Perspective

The simplest way to understand the environment of the classroom is to ask the teacher. They are able to report on what they do, the interactions they create, and the extent to which their students are engaged in the classroom. The key is how accurate are they in reporting on these elements. There is ample evidence to suggest that teachers are much more accurate in describing quantity information (how often they use a strategy) than quality information (how well its strategies are implemented). This is particularly true when teachers are asked to report on more specific information like their interactions with students, and their students' perceptions of engagement. Typically, correlations between teacher and student reports of engagement are very low. However, there is evidence to suggest that aspects of teacher report, particularly those related to connection with students, have an influence over student reports of engagement and enjoyment in the classroom (see Skinner and Belmont, 1993).

There is also the question of how does the impact of capturing the teacher's perspective change depending upon the age of the students. In surveying the participants in a K-3 classroom, the indicators of an effective classroom may only be reliably captured by asking the teacher. Students at that age are likely to only be able to accurately report on 'do you like your class/teacher' rather than different features or aspects of the classroom environment. Thus, capturing the dynamics of an effective classroom in pre-K or early elementary grades should involve a combination of teacher report and as much observation as time/cost allows, while the utility of teacher reports may wane as students get older.

Understanding the Classroom from an Observer Perspective

A focus on classroom interactions is the centerpiece of observational measures that are strongly linked to the positive development of students. Though observations of classrooms are more costly than teacher or student report, they offer an independent view into what makes a classroom environment effective. With the rise in available technology over the last decade, video-recorded observations can be used to visually show teachers the behaviors and interactions that are most strongly linked to increases in student engagement and learning. Two systems that have recently seen vast implementation in pre-K-12 settings are the Classroom Assessment Scoring System (CLASS; Pianta et al., 2010) and the Framework for Teaching (FFT; Danielson, 2007).

The CLASS is a tool for observing and rating the interaction quality among teachers and children in classrooms. Following the Teaching through Interactions framework, it measures teachers' emotional, organizational, and instructional supports that research indicates contribute to children's social development and academic achievement. The tool is used to assess interactions between teachers and children for a variety of purposes, including teacher professional development, monitoring and evaluation, and research. The CLASS focuses on interactional processes, and captures *how* materials and curriculum are implemented. The CLASS is based on both developmental and educational theory. It evolved from instruments developed and used in the large-scale National Institute of Child Health and Human Development Study of Early Child Care, including the Observational Record of the Caregiving Environment and the Classroom Observation System. The CLASS has since been validated by over 10 years of research in educational settings, directly connecting teacher–child interactions with growth in children's academic and social skills. An early version of the CLASS was used in the National Center for Early Development and Learning Multi-State Pre-K Study and Study of Statewide Education Programs. These two studies evaluated over 700 state-funded pre-K classrooms in 11 states, and included classroom observations; child assessments; and surveys of teachers, parents, and administrators (e.g., Pianta et al., 2005). The extensive use of the CLASS in these studies and others has led to further refinements in the tool's development and construction.

While the CLASS was initially developed for use in pre-K classrooms, it has since been expanded for use in classrooms for both older- and younger-aged children. The majority of studies on the reliability and validity of CLASS come from its roots in pre-K settings. Widely employed in research and evaluation studies, the CLASS has been affirmed as a reliable and valid measure through use in over 3000 classrooms in Head Start, child care, and pre-K settings (both center- and school-based). However, recent studies including the large Measures of Effective Teaching (MET; Kane et al., 2012) study funded by the Bill and Melinda Gates Foundation have tested the reliability and validity of CLASS in K-12 classrooms. There is now considerable evidence that the dimensions of the CLASS, particularly those tapping emotional and instructional interactions, are consistently linked to the social, emotional, and academic development of students (see Hamre and Pianta, 2010 for review).

The FFT was also included in the MET study and has been implemented as both a research and an evaluative tool (see Danielson, 2011 for review). The FFT is a research-based set of components of instruction, grounded in a constructivist view of learning and teaching. It is organized as a holistic approach to the school setting, where the complex activity of teaching is divided into 22 components (and 76 smaller elements) clustered into four domains of teaching responsibility: (1) planning and preparation; (2) classroom environment; (3) instruction; and (4) professional responsibilities. The structure of the classroom environment and instruction domains is very similar to the CLASS in that it focuses on behaviors that promote a positive and respectful climate, effectively managing student behavior, and consistently using questioning and discussion to promote engagement in the classroom.

Understanding the Classroom from a Student Perspective

One of the most prevalent sources of information about classrooms in educational research comes from student reports. Indeed, one might argue that the best source of information about the effectiveness of a classroom environment comes from the individual students in that classroom (Weinstein, 1983; Ames, 1992). However, caution should always be used when analyzing student reports as they are prone to false interpretation. Particularly since as children get older, their reports of the classroom (at least those taken early in the school year) may be more strongly influenced by previous experiences. For example, one study found that average classroom engagement levels in the beginning of the school year (taken from student reports of engagement) were negatively correlated with observations of classroom engagement during the same period ($r = -0.19$), whereas those same correlations measured at the end of the school year indicated much greater agreement ($r = 0.39$; Hafen et al., 2012). The bulk of the fluctuation in these correlations is due to variation in how students within the same classroom view the effectiveness of classroom interactions. Despite this, student reports of the classroom have indicated several markers through which healthy development occurs.

Once students reach the upper elementary grades, they are more capable of reliably reporting on their experiences in the classroom. In other words, older students are more likely to

agree on the relative degree to which they experience certain teacher practices (although there is rarely perfect agreement; see Miller and Murdock, 2007 for a discussion of the reliability of student reports). This provides an excellent opportunity to understand an effective classroom from the student perspective. Approaching classroom quality from the premise that an effective classroom will meet the developmental goals of its students, self-determination theory provides a useful developmental framework to conceptualize a student's self-motivation and well-being (Ryan and Deci, 2000). Self-determination theory includes three basic needs: competence, relatedness/connection, and autonomy (Reis et al., 2000). The need for competence is satisfied by the feeling that one can successfully produce desired effects and outcomes. The need for relatedness is derived from the experience of feeling close and connected to others one considers significant. The need for autonomy involves the perception that one's activities and environment are matched and endorsed with the self. Each of these three needs outlined in self-determination theory have been linked to various indicators of achievement and adjustment inside and outside the classroom (Deci et al., 2001; Denissen et al., 2007; Roeser et al., 1998).

The conceptualization of student experiences in the three core areas of self-determination theory is similar to the Teaching through Interactions framework in that the actions of the teacher could reasonably translate into perceptions by the student: higher levels of emotional support from a teacher would likely result in higher student reports of relatedness and connection; higher levels of organizational support would presumably lead to higher student reports of autonomy; and higher levels of instructional support should lead to students reporting more competence over time. This process of connective instruction should be the core of any measure of classroom quality, and the most effective strategy for assessing the effectiveness of the classroom environment is to look for overlap between multiple perspectives: teacher, student, and observer.

Understanding the Classroom from Multiple Perspectives

As detailed above, studies of the effective components of the classroom have yielded support for frameworks like Teaching through Interactions and self-determination theory because they highlight the importance of eliciting a student's emotional connection to the *teacher*, the *content*, and the *instruction*. The process of eliciting student connections, also called connective instruction, emphasizes the importance of these three facets in understanding and predicting student engagement (Martin and Dowson, 2009). Forming an emotional connection to the teacher occurs through interactions in which the teacher affirms and displays a genuine interest in the student's perspective and gets to know each student as an individual. Forming an emotional connection to the content involves opportunities to work with material that is relevant to a student's life and that has meaningful purpose. Forming an emotional connection to instruction is characterized by opportunities to learn from mistakes and develop a sense of competence. This framework aligns with the Teaching through Interactions framework, as they both posit that an effective classroom environment is created by the interactions teachers have with students along emotional, organizational, and instructional domains.

A recent study extends this theoretical argument by positing that identity development sits at the center of the connective instruction model of effective classrooms (Cooper, 2014). In this study, a mixed-methods approach was employed collecting data from 581 different classrooms totaling 1132 of the school's 1420 students through a self-report survey, and then following up with case studies of five classes that were intended to be representative and "provide insight into how the various types of teaching practices related to engagement" (p. 12). Results suggested quite strongly that connective instruction practices emphasizing the uniqueness of students by connecting understanding, affirmation, and humor with expressions of relevance and self-expression were most strongly associated with student engagement. This study highlights the important point that emotional engagement achieved through positive affect and emotional connections with teachers are only predictive of greater learning when paired with high-quality instruction that pushes higher-order thinking (Marzano and Pickering, 2011).

Impacting the Effectiveness of the Classroom with Professional Development

In order to enhance students' experiences in school, it is necessary to not just measure but also to improve interactions between teachers and students. However, improvement is often difficult, and independent reviews of professional development often find little to no evidence of validated and consistent approaches to improving teacher–student interactions (see http://ies.ed.gov/ncee/wwc/PDF/WhtPapers/wwcreviewprocess.pdf). Increasing evidence from the research literature suggests three features are vital to improving teacher–student interactions: (1) all individuals in a school must have a common vision and shared goals about how to create an effective classroom; (2) there needs to be a reliable and valid mechanism in place to measure classrooms that aligns with the shared goals within a school; and (3) teachers and other school personnel need access to professional development experiences that are effective in making progress toward these goals. A well-defined classroom observation system can assist in addressing all of these factors.

To the first feature, that of a shared vision and goals for creating effective classrooms, we know that in a typical school there are probably as many definitions of effective practice as there are professionals in the building. Without a shared vision of effective practice, communication between teachers and administrators and among teachers is likely to be unproductive. A reliable and validated observational protocol provides school personnel with a shared definition of effective practice and a common method for looking for these practices in the classroom. Importantly, by using a reliable and validated tool (i.e., one that has shown capacity for consistent use across observers and across time, as well as a relation to desired student outcomes), teachers and administrators can have confidence that their shared definition of quality practice is

focusing them on the types of classroom interactions that really make a difference for students.

With regard to the second feature, which is the need to have an appropriate measure, the explicit purpose of a classroom observation system is to assess the standing of classrooms in relation to the types of classroom interactions deemed relevant for student success. Using reliable and valid tools to observe and rate classrooms provides a research-based mechanism that can facilitate systematic increases in educational quality. Direct assessments of teaching practices based on reliable and valid metrics combined with commonly utilized assessments of effective teaching (such as student standardized test scores, or teacher value-added metrics) can create a robust basis for accountability efforts. Taken together, observational and value-added metrics can provide data that directly inform individualized and targeted programs of professional development, discussed below.

The third feature that facilitates improvement in teaching practice is access to professional development that offers ongoing training, support, and feedback. Identifying areas of strengths and challenges based on classroom observation scores can provide information about school-level instructional weaknesses that can be targeted for intensive in-service trainings. Furthermore, profiles of the strengths and areas of challenge for individual teachers provide a useful starting point for individualized professional development plans that target improvements in specific areas of teaching practice through the provision of support and constructive challenge.

The frameworks presented (Teaching through Interactions, self-determination theory, connective instruction) in this article indicate that an effective model of professional development for teachers must include a focus on interactions. One such model that has received empirical support for improving the classroom environment and ultimately student achievement is MyTeachingPartner (MTP). MTP targets the quality of teacher–student interactions. The program is designed to guide teachers in creating emotionally positive, motivating, and cognitively challenging classrooms characterized by sensitivity to individual students' socioemotional and academic needs (see Pianta et al., 2008). The additional value of this model is that it has been successfully implemented with teachers from pre-K to 12th grade. A key focus of MTP is that it offers teachers *ongoing, personalized* coaching and feedback that is grounded in a common instructional framework. MTP was originally designed to accompany the CLASS framework, though recent iterations have utilized frameworks that are idiosyncratic and district-specific. The model uses video from the classroom, and thus the focus is always on specific interactions that impact students in the classroom.

Research evidence suggests that MTP is successful at producing desired outcomes across grade levels. Early work demonstrated effectiveness in preschool programs (Mashburn et al., 2008; Pianta et al., 2008). More recent work has demonstrated efficacy in middle and high school, and the ability to deliver MTP consistently at scale (LoCasale-Crouch et al., 2011). In a randomized control trial of MTP conducted with 78 middle and high school teachers and over 1400 of their students, teachers who participated in the MTP condition had significantly better interactions as measured by the CLASS, controlling for where they were at the beginning of the year (Allen et al., 2011). Critically, end-of-course, standardized state exam scores for students whose teachers were in the MTP condition were higher than those for students in control classrooms 1 year after the intervention. This significant difference equated to an average increase in student achievement from the 50th to the 59th percentile for a student moved from the control condition to the MTP condition. MTP participation was also associated with increases in observed student engagement (Gregory et al., 2014) and positive peer interactions (Mikami et al., 2011). This evidence provides promise in that teachers are able to improve classroom effectiveness when provided specific, ongoing, and relevant feedback using a consistent framework.

Conclusions

The most effective classrooms have teachers that recognize the developmental needs of their students and structure learning opportunities accordingly. This is not typically taken into account in the current educational system, as teachers are typically pressured to improve their instruction around content for standardized tests rather than being given opportunities to learn how to deliver content in ways that will engage and motivate their students. A renewed focus on developmentally appropriate interactions (e.g., increased autonomy for adolescent students) has the power to yield increases not only on student learning and achievement, but also on students' emotional and social development. Through this focus on classroom interactions, it is clear that effective classrooms are those that help students develop into effective people.

Climate Change

Abstract

Climate change has become an important social and policy concern in recent years, chiefly as a result of scientific warnings about the potential effects of anthropogenic climate forcing on ecological systems, human health, water supplies, agriculture and land-use, economic performance, and security. Three main themes in social and behavioral scientific research on climate change are surveyed: the challenges of communicating the complexities and uncertainties of climate science to political and public audiences; developments in the governance of climate change at the international, national, and transnational levels; and individual perceptions of, and responses to, climate change.

Introduction

Climate change is recognized as a major environmental problem by a majority of the international scientific community. According to the Intergovernmental Panel on Climate Change (IPCC) Fourth Assessment Report (IPCC, 2007: 2): "global atmospheric concentrations of carbon dioxide, methane and nitrous oxide have increased markedly as a result of human activities since 1750 and now far exceed pre-industrial values." The report further suggests that most of the observed increase in global average temperatures since the mid-twentieth century is very likely due to rising anthropogenic greenhouse gas concentrations and that, if not controlled, climate effects such as rising sea levels, disruption to weather patterns, and ocean acidification pose serious to human health, water supplies, agricultural systems, economic performance, and global security. Such projections have triggered calls for prompt and coordinated action to reduce greenhouse gas emissions and adapt to changes in the climate system (Stern, 2007).

Research on climate change in the social and environmental sciences in many ways mirrors these concerns. Three main themes emerge within this body of research and form the mainstay of this article. The first concerns the communication of climate science to political, business, and public audiences. Although human-induced climate change is almost universally recognized by scientists, it is not a discrete or easily observable entity; rather, it is a social construct used to represent an array of phenomena, cause-and-effect relationships, and projections about the future. A key focus for social scientists has thus been how the technical and uncertain science of climate change is being translated and conveyed to nonspecialist audiences and how different messages and communication methods influence how climate change is comprehended and viewed.

A second theme concerns the governance of climate change. The long-term and potentially far-reaching effects of climate change suggest the need for a global-level response but, so far, a strong international deal to reduce greenhouse gas emissions has proven elusive. The reasons for this have been an obvious preoccupation, as has analysis of climate governance at the national level. Since the late 1990s, however, state-focused analyses have been complemented by studies examining the involvement of subnational authorities, private corporations, and civil society groups in climate governance, drawing from other work on the governance turn in the social sciences. Third, disciplines such as behavioral psychology have explored how individuals comprehend and respond to climate change. Building on general models of environmental behavior developed from the 1970s onward, this work has also investigated opportunities and barriers to integrating 'climate-friendly' behaviors, such as reducing energy consumption and low-carbon transportation, into everyday life practices.

Communicating Climate Change

Scientific Reporting

One aspect of climate-change communication that has received considerable research interest focuses on the role of scientific authority and consensus in supporting the construction of an effective global response to climate change. The theory of epistemic communities upon which much of this research is based rests on the observation that environmental problems, like many other global problems confronting contemporary leaderships, are highly complex and their effects extend beyond the issue area to which they ostensibly relate. In this particular case, climate change is not just an environmental policy problem; it has far-reaching implications for policies affecting energy production, transport, manufacturing, water supplies, and land-use and agriculture. This complexity breeds uncertainty in the mind of policy-makers on questions of risk and how to define national interests in the formulation of foreign and domestic policy. Under such conditions, politicians and their bureaucracies have strong incentives to seek advice from recognized bodies of expertise held in common by *epistemic communities*.

An epistemic community is defined as a transnationally organized but nationally embedded network of professionals that possess an authoritative claim to policy-relevant knowledge within their domain of expertise. In order for reporting to governments and policy elites to be effective in building successful environmental regimes, epistemic communities need to have four main qualities (Haas, 1992):

1. a shared set of normative and principled beliefs;
2. shared causal beliefs derived from an analysis of practices that have led to an environmental problem or set of problems;

3. shared notions of validity based upon internally defined criteria for weighing and validating authoritative knowledge; and
4. a common policy enterprise prompted by conclusions arising from the above.

These qualities have been observed in numerous studies of relatively successful attempts at environmental governance, such as the Mediterranean Action Plan and the Ozone Layer Protection regime. Quite naturally, it was hoped that such examples might be reproducible in other areas of global environmental governance.

Haas' model can help explain why most of the world's governments took scientific reporting of climate change seriously and signed the United Nations Framework Convention on Climate Change (UNFCCC), developed as part of the Rio Earth Summit held in 1992. The discipline of meteorology established the preconditions for a climate epistemic community in that it developed norms and institutions for international scientific cooperation well before questions of anthropogenic influence upon the climate system were discussed. The common interest among European maritime states in understanding climate patterns further enabled meteorology to develop norms and institutions for sharing, validating, and weighing knowledge. Arrhenius theorized the possibility of human activity as a cause of climate change as early as 1896, but it was the epistemic community that had developed norms for collecting, sharing, and evaluating meteorological knowledge that was responsible for verifying climate data, recognizing climate change as a problem, and bringing it to the attention of the international community at the World Meteorological Conference in Toronto in 1988 and subsequent international meetings.

The epistemic community model became less compelling once formal international climate negotiations started under the UNFCCC (Paterson, 1996). In some cases an epistemic consensus may diagnose an environmental problem that can be solved through technocratic means. In other cases environmental problems appear to cross a threshold of complexity where the epistemic community founders upon normative and political issues. One way to illustrate this with regard to climate change is to examine the division of labors between the three main working groups of the IPCC, the international scientific body appointed by governments to investigate and synthesize scientific research on climate change.

With painstaking work, and despite well-financed opposition from some sections of the fossil-fuel lobby, Working Group I has delivered a series of scientific consensus reports on the scientific basis of climate change and the need to mitigate its anthropogenic causes in 1991, 1997, 2001, 2007, and 2013. These reports have been an important factor in persuading national politicians and bureaucracies in signing up to a 'motherhood' convention for stabilizing the growth in concentration of greenhouse gases, the UNFCCC. It has proven more difficult, however, for working groups to secure consensus at high levels of scientific certainty with regard to forecasting the differential impacts of climate change upon human societies living across different regions of the world. This is a key issue for international negotiations because the lack of certainty creates high levels of difficulty for securing a political agreement on issues such as whether developing countries that bear the least responsibility for historical emissions of greenhouse gases should attempt to curb their emissions or whether developed countries should take a policy lead or compensate developing countries for the effects of climate change.

It has proven even harder for Working Group III to draft a convincing report that conveys 'a common policy enterprise' on appropriate responses to mitigate and adapt to climate change. The main reason for this is that developing policy recommendations requires the mediation of many ontological positions (e.g., by what measures can the effectiveness of a policy be measured?), ideological tensions (e.g., strong government intervention or more market-based approaches), and political conflicts (e.g., when policy responses impose costs of citizens and industry) that are highly impermeable to resolution using positivist methods. Particularly but not exclusively in relation to offering policy solutions, there are limits beyond which a climate epistemic consensus can fragment into a plurality of *communities*. Working Group III has often attracted criticism for the timidity of its proposed policy options, and for creating a tacit boundary line that excludes some more radical proposals for reforming institutions and the structure of international political and economic governance from consideration by governments (O'Riordan and Jordan, 1997).

Nongovernment Organization Campaigns

A second area of communicating climate change focuses on nongovernment organization's (NGO) involvement in communicating climate change to public audiences as part of efforts to build social movements for change. Some research on this topic comes with an explicit or implicit critique of epistemic or 'policy network' approaches alleging that they overestimate the role of experts and understate that of environmental movements (Toke, 1999). According to this line of reasoning, scientists and policy experts can produce reports for governments but real progress in mitigating and adapting to climate change requires political leaders to be compelled to override countervailing interests by sustained pressure from below.

Diani and Donati (1999) map out some ways NGOs might mobilize civil society in the pursuit of environmental objectives and the quandaries these tactics create. For instance, groups seeking to campaign for action commonly face a dilemma between seeking cash membership for funding a professional lobby and seeking mass membership to help enable participatory action. Likewise, activists may face a choice between advocating conventional protest and pressure, and an alternative repertoire that promotes civil disobedience or disruptive protest. Each choice has advantages and disadvantages, so activists have tended to carve out niches within the NGO ecosystem. First, there is the public-interest lobby or think-tank model with professional staff and expertise but low member participation. Second, there is the participatory-pressure model, which seeks to involve rank-and-file membership but uses conventional pressure tactics. Third, there is the professional protest organization model that cultivates mainly passive membership to finance professional activism, using confrontational and disruptive tactics as well as conventional ones. Finally, there is the participatory-protest organization approach, which uses a mass membership,

low-hierarchy model and utilizes grassroots protest, civil disobedience, and disruptive tactics to incur lower costs.

Wapner (1995) further examines the ways in which a large number of NGOs have pursued opportunities to expand their role through the emergence of global civil society. This approach envisages that NGOs may seek both to pressurize national governments on climate change and to become international actors in their own right. Some environmental NGOs command larger annual budgets than those of intergovernmental organizations (IGOs), such as the United Nations Environmental Programme. They can also mobilize a level of cross-national support that many states and IGOs would struggle to match. Maurice Strong, General Secretary of the United Nations Conference on the Human Environment (held in Stockholm in 1972) and the Rio Earth Summit of 1992, consciously pushed for greater involvement by NGOs in these summits to pressurize state delegations and raise the profile of NGOs in the global media. This initiated a tradition that has continued in climate diplomacy, with engagement by NGOs beyond the protests and fringe debates that have become regular features of international climate summits. NGOs now regularly attend UNFCCC Conference of the Parties meetings as observers, advisors to delegations, critical commentators, and as conveners of side events. Many environmental NGOs also receive funding from IGOs for delivering or assisting sustainable development projects linked to climate mitigation and adaptation. One concern in the literature relates to the trade-offs between independence and influence that accompany the institutionalization of NGOs (Chatterjee and Finger, 1994). Other debates arise about differences in objectives and tactics between climate-related environmental movements based in the global North and South. Much North–South NGO networking has had very positive results, however, such as the discovery that the reporting of indigenous knowledge of climate change can be extremely powerful. The intimacy of many indigenous communities with nature and their dependence upon it lends their observations a human dimension that reaches audiences in ways that scientific reports never could.

Media Reporting of Climate Change

A third arena of climate-change communication relates to mass media reporting of climate issues. Public audiences obtain most of their information about scientific and political issues from newspapers, television, or the Internet. As such, how different mass media report climate change has strong potential to influence not just public attitudes toward the existence and seriousness of human-induced climate change, but also toward government performance in managing the issue as political life is increasingly conducted in the media spotlight (Gavin, 2009). The complexities of the relationship between science, public opinions, and politics have led to keen interest in how the mass media reports climate change and how this reporting affects social and political debate. Boykoff and Boykoff (2007: 1190) argue that: "mass-media coverage of climate change is not simply a random amalgam of newspaper articles and television segments … it is a social relationship between scientists, policy actors and the public" that is mediated through a series of journalistic norms. These include the *personalization* and *dramatization* of stories to increase their appeal, and the notion of *journalistic balance*, whereby the media seek to provide 'fair' and 'objective' coverage on issues where there is significant uncertainty or dispute by giving both sides of the argument roughly equal attention (Boykoff, 2011).

The scientific uncertainties encircling climate science potentially reduce its newsworthiness; however, personalizing and dramatizing climate change by focusing on geo-hydrological hazards, such as flooding or 'freak' weather events, and human interest stories during such events, provide powerful devices for gaining public attention and boosting sales. Dramatization has also become prominent in media reporting of the future effects of climate change. Doulton and Brown (2009) analyzed UK 'broadsheet' newspaper reports on climate change between 1997 and 2007 and report that discourses of *optimism* (climate change may bring benefits to parts of the world) and *rationalism* (other development priorities should be addressed first) have steadily been displaced by discourses emphasizing *climate change as a potential catastrophe* for developing countries to press for greater action by wealthier nations to reduce emissions and assist poorer countries in adapting to future climate changes.

Balanced reporting is a further device which can be used to add drama and conflict to stories. However, it can also create a false sense of controversy about climate change by placing the minority of scientists who are skeptical about climate change or human influence on the climate on a roughly equal footing with the majority of scientists who accept the major tenets of anthropogenic climate change. Under such circumstances, balanced reporting may produce biases in public opinion and political debate, particularly where media outlets have political motivations and use it to criticize governments. Geographical variations in balanced reporting have formed a further focus for scholars interested in the influence of the mass media on national climate policy. Boykoff (2011) notes a greater prevalence of balanced reporting on climate change in sections of the United States newspaper and television media compared with the United Kingdom that may help to explain the difficulties in creating domestic climate legislation in the United States. Dunlap and McCright (2011) similarly note the growing influence of the blogosphere as an unregulated arena for 'balanced' reporting even where major outlets follow the scientific consensus on climate change.

Just how far mass media influences public concerns about climate change, though, remains an open question. Boykoff (2011: 71) argues that: "the media don't tell people what to think, but they tell them what to think *about*." Thus, media reporting may shape public opinion on climate change less directly than is sometimes presumed but may affect it in subtler ways, via the level of attention given to the topic and the specific issues citizens are encouraged to consider, e.g., scientific uncertainty or the case for political or social action. The situation is complicated further by the so-called issue–attention cycle popularized by Anthony Downs (1972). Downs argued that environmental issues may fade from public and political attention before they are resolved (**Figure 1**), but suggested that environmental concerns may be eclipsed at a slower rate than most issues because of their visibility and widespread effects. The long-term nature of climate change may therefore give rise to periods of more intensive media coverage followed by

Figure 1 The issue–attention cycle.

interludes of relative inattention, with each cycle producing different effects on public and political opinion.

Governing Climate Change

International Climate Negotiations

In a comparative analysis of global governance, political theorists from the liberal institutionalist tradition have observed that successful international regimes tend to evolve through three main stages (O'Neill, 2009). Initially, there is an agenda-setting phase where common problems are identified and reasons for international action are developed. In the second phase, states meet to agree the principles, norms, rules, and decision-making procedures for a legal treaty or framework convention. Third, states move into a phase of regime strengthening, whereby negotiations work toward supplementing the framework convention incrementally through further agreements.

The history of climate diplomacy appears to fit the first two stages of this model. A dialogue between scientists and policymakers initiated climate negotiations during the 1980s and informed the drafting of the UNFCCC signed at the Rio Earth Summit in 1992. The climate regime then sought to embark on stage three in 1997 with the creation of the Kyoto Protocol. Thereafter, the story darkens, arguably reaching a nadir at the failed climate negotiations in Copenhagen in 2009 from which ongoing climate negotiations under the UNFCCC have struggled to recover (Falkner et al., 2010).

Political theorists from the neorealist tradition tend to direct their analysis toward less successful regimes. Neorealists acknowledge the existence of international cooperation but stress the systemic obstacles and structural barriers to its long-term success and longevity (Grieco, 1988). A key barrier is the anarchical structure of world politics, whereby states are compelled to compete with each other for wealth, power, and status in the pursuit of state security. This results in the construction of national interests that make it difficult to sustain genuine international cooperation. Such analysis could arguably be applied to the progress of climate diplomacy since 1997, where reasons of national interest are identified as contributing to durable fault-lines in the politics behind the negotiations.

First, conflicts arise out of the structure of energy interdependence in a hydrocarbon age (Paterson, 1996). States dependent on fossil fuels for export income such as the Oil Producing and Exporting Countries (OPEC), for example, are often found amongst the laggards in climate negotiations. Similarly, political leaders in of states that possess hydrocarbon-intensive economies based on ample domestic supplies, such as the United States, Canada, and Australia, have frequently cited their national interests in their resistance to binding targets on carbon emissions. Conversely, states with economies that are highly dependent upon hydrocarbon imports (notably some member states of the European Union) tend to be more inclined to support initiatives to mitigate climate change through multilateral agreements to reduce dependency on fossil fuels.

Second, there are tensions arising from inequalities in levels of vulnerability or adaptive capacity to climate change. Small island states, states with large low lying coastal areas (e.g., Bangladesh), states facing water-scarcity problems, or states which are predicted to be most vulnerable and least able to respond to climate change, such as many African countries, have advocated more rapid progress in strengthening the climate regime after the Kyoto Protocol. States that perceive themselves to be less threatened by the consequences of climate change, either through geographical accident or because of their wealth and adaptive capacity, arguably pursue negotiations with less urgency (Leiserowitz, 2007).

Third, North–South questions of climate justice have also complicated progress in the UNFCCC negotiations. This was already acknowledged in the Framework Convention principle of 'common but differentiated responsibilities.' Key articles in the Framework Convention also assimilate the norm of sustainable development and stress the need for poorer countries to pursue development while the world's richer nations lead efforts to decarbonize their economies. Attempts to mediate this fault-line have only been marginally successful, however, as differences perennially reemerge whenever attempts are made to translate these principles into specific carbon-emission commitments. The United States, for example, has long maintained that when it comes to interpreting the idea of common but differentiated responsibilities, its own historic, present, and future carbon emissions should be placed into perspective against the burgeoning emissions of newly industrializing countries, particularly China and India. Conversely, these countries and members of the G77 (the negotiating collective for developing nations in the UNFCCC system) have argued that common but differentiated responsibilities should take into account the question of historical contributions and national per capita emissions (Hurrell and Sengupta, 2012). North–South tensions have also emerged over aid for capacity building, technology transfer, and adaptation. Some southern states have remonstrated that their capacity to act is being eroded by unequal political and economic relations with the North, and are reluctant to pay excessive premiums for mitigation technologies developed in the North. They have also argued that agreements should recognize the need for adaptation finance as reparations for climate change already are in the pipeline, and that aid should also be provided where southern states are asked to forgo development to preserve natural carbon sinks such as the Amazon rain forest. Conversely, some northern states have

been reluctant to concede to climate change related aid demands, partly on the suspicion that they attempt to revive proposals made by developing countries for a New International Economic Order of reformed trade relations and increased development assistance that were roundly rejected by developed countries in the 1970s, and partly on the grounds that the emergence of countries like China, India, and Brazil as economic powerhouses make these calls redundant.

While neorealist explanations for the slow progress of international climate diplomacy are well recognized, some utilize constructivist theory to argue that the anarchic nature of the international system may drive states to pursue their national interest while pointing out that national interests are contingent rather than fixed. States are capable of learning, and of redefining their interests, for example, by placing greater emphasis on security risks presented by climate change, as they receive and interpret new information.

Governing Climate Change at the National Level

The UN climate negotiations establish the basic structure of commitments and mechanisms for international cooperation on climate change. However, substantive policies to reduce greenhouse gas emissions are primarily enacted at the national level. Several strands of enquiry have been pursued to understand the processes through which states seek to govern climate change. First, studies in the comparative politics tradition attempt to identify how general national characteristics, such as per capita wealth, education, dependency of fossil fuels for energy production, press freedom, and domestic environmental groups explain the strength or weakness of national climate policies. For instance, Harrison and Sundstrom (2007) examine the effects of electoral incentives, compliance costs, pressure from domestic interest groups, the concentration of governing authority within the country, and international influences (e.g., from UN negotiations or multinational corporations). The conclusions from such research have been somewhat inconclusive. Compliance cost emerges as a significant determinant of whether countries introduce domestic climate policy but is not decisive in all cases. Similarly, public opinion appears to have been important in persuading politicians to act on climate change in the EU, Japan, and Australia but has been less influential in the US, Canada, and Russia.

A second strand of investigation has examined the learning and diffusion processes involved in developing new ways of governing climate change. Hall (1993) distinguishes three main types of policy learning contributing to policy change: *technical learning* (learning within fixed policy objectives to improve policy effectiveness, cost-efficiency, and/or equity); *conceptual learning* (where decision-makers engage in deeper reflection about policy problems, policy goals, and the strategies used to pursue them); and *social learning* (where social debates on policy problems lead to learning by policy-makers about society's preferences and their adoption in policy). Lenschow (2005) identifies that such processes may be informed by some combination of past experiences (*lesson drawing*); experiences of others (*diffusion and emulation*); new information; or technological developments affecting the policy options available to decision-makers. Utilizing such concepts, Voβ (2007) examines how the framing of carbon trading as an effective and cost-efficient policy instrument for reducing greenhouse gas emissions contributed to the European Union's decision to adopt an EU-wide carbon-trading scheme in 2005. Related analysis has sought to explain the conditions causing the uneven uptake of new climate policies in different countries. Among the main factors examined are: attributes of the policy (including its complexity, trialability, and relative advantage over previously used instruments); and whether new types of climate policy 'fit' or clash with existing national institutional procedures and preferences (Makse and Volden, 2009).

Despite the insights provided by these approaches, both could be criticized for taking a rather apolitical view of climate policy when, in reality, climate change has become a politically charged issue in countries like the United States and Australia, where (generally) right-wing political parties and energy-intensive industries have enjoyed considerable success in blocking new climate legislation. Similarly, internal opposition to measures that threaten the development ambitions of industrializing countries (e.g., China and India) has been noted by Stern (2007). Most of the literature that has engaged more explicitly with the political dimensions of climate policy has adopted a descriptive or critical approach, charting current trends or censuring governments for prioritizing economic performance over climate protection while examining climate policy through the lens of existing political and economic mind-sets (Harris, 2009). Compston (2009) and Bailey and Compston (2012) provide more direct analysis of political barriers facing national governments on climate policy. These include: fear of electoral retribution, loss of competitiveness if other countries do not introduce comparable measures, business threats to withdraw investment, and the influence of climate 'sceptics' on political and public debates on climate change. Political strategies to counter these risks include: (1) ensuring new climate policies are designed to be as effective and cost-efficient as possible in reducing emissions; (2) emphasizing the cobenefits of climate policy (e.g., competitive advantage in low-carbon technologies and the health benefits of reducing emissions) rather than climate change itself to create a broader support base for policies; (3) developing 'package deals,' where politicians appease opponents by offering concessions in other policy areas; and (4) increasing the political clout of climate change relative to other interests by amalgamating climate and energy ministries and appointing high-profile scientists to high-level committees to encourage balanced debate between science and business interests on climate change.

Governing Climate Change Transnationally

A final sphere of climate governance to come under scrutiny is so-called *transnational* climate governance, a term coined to describe various types of public–private partnerships and networks involved in governing aspects of climate change that operate outside the control of national governments. Interest in transnational governance has stemmed principally from the recognition that globalization and the introduction of neoliberal reforms across numerous sectors and jurisdictions has resulted in a significant dispersal of governance activities (and

authority) away from nation-states to subnational authorities and nonstate actors, including corporations and NGOs.

Many lines of enquiry have again been pursued, but much interest has centered on: (1) the types of actors involved in these 'new' governing arrangements; (2) the ways in which new institutions, forms of cooperation, and political spaces are emerging in response to the limitations of state-centered climate governance; and (3) the governance functions performed by these networks. Andonova et al. (2009) provide a typology of the main actors and governance functions involved in transnational climate governance, where they stress the multiple forms of public- and private-sector authority and the use of multiple governing mechanisms, ranging from informal cooperation (e.g., information sharing) to capacity building and implementation (e.g., providing finance, expertise, labor, technology, or monitoring) to more formal rule-setting.

A first pivot of investigation has been the rapid growth since the mid-1990s in *subnational governments* and *local communities* working to place climate change on local agendas, and the consolidation of individual efforts by initiatives like Cities for Climate Protection that promote international information and resource pooling, and the creation of political identities that can enable 'local' actors to press for stronger national action on climate change (Betsill and Bulkeley, 2007). North American subnational administrations have been particularly active in developing local and regional initiatives such as the Californian emissions trading scheme and the Western Climate Initiative, a regional scheme covering several US states and Canadian provinces aimed at developing market-based solutions to climate change and laying the ground for a North American carbon market. Significant attention has also been directed at private-sector initiatives. These range from schemes encouraging individuals to pay to offset the carbon emissions from activities such as flying and the Carbon Disclosure Project (CDP), a not-for-profit organization that encourages companies and cities to disclose their emissions performance and share information about their climate-related activities (Newell and Paterson, 2010). The philosophy behind the CDP is that revealing such information helps companies to manage climate risks strategically while providing decision-makers with data and insights to develop policies that meet business and environmental needs.

Alongside chronicling the rise of climate governance networks, more critical questions have been posed about their effectiveness and implications for the state as a 'traditional' source of governing authority. Market-based approaches like the Clean Development Mechanism and voluntary carbon offsets that operate by financing emissions-reduction projects in developing countries have been criticized for methodological and governance deficits. For instance, determining whether projects such as afforestation produce additional emissions reductions depends on counterfactual arguments about what would have happened if the project had not gone ahead. A further problem is that markets tend to draw investment toward the most lucrative emissions-reduction options (the 'low-hanging fruit') and arguably reduces the pressure on developed countries to reduce their own emissions (Newell and Paterson, 2010). The broader concern is that the interests of smaller developing countries are poorly served compared with those of more powerful countries, major corporations, and multilateral institutions. The credibility of market-based approaches thus rests on effective governance in relation to target setting, accounting methodologies, lines of accountability, and sanctions against those that infringe the rules. The value of city and regional initiatives, meanwhile, rests on their ability to expand sufficiently that they make a worthwhile difference to global emissions trends or provoke stronger national or international action.

Most commentators agree that transnational governance is creating more interconnected and in some ways less top-down relationships between state and nonstate actors but has not diminished the state as a critical actor in climate governance (Bulkeley and Jordan, 2012). State involvement is even intensifying in some areas as governments and international bodies develop new legal and monitoring regimes to ensure carbon markets achieve climate objectives. Equally, states possess formidable informational and implementation capacities that provide essential legal support, credibility, and financial and other resources to transnational partnerships. As such, the growth of private and hybrid systems of climate governance may be transforming statehood, but does not appear to be undermining it.

Climate Change and Personal Behavior

Much work on the communication of climate change and climate governance rests upon certain assumptions about the mainsprings of human behavior. One common assumption is that the critical challenge in engineering more 'climate-friendly' forms of human behavior is to address current information deficits about the climate issue. According to this line of reasoning, once people have accurate information, attitudes will change and more appropriate patterns of behavior will emerge (**Figure 2**). Another common assumption is the idea of the 'rational actor model,' which assumes that people, states, and businesses are rational beings that calculate their self-interest based on all the information available to them. Sociobehavioral research in disciplines such as behavioral psychology supplements and in some respects challenges these assumptions.

A core strand of this research focuses on the so-called 'value-action gap.' This term refers to cases where individuals are well

Figure 2 The information deficit model.

informed about climate science and share common values about what needs to be done about climate change, but this fails to have any impact on personal behaviors (Kollmuss and Agyeman, 2002). The question therefore arises as to how to explain situations where perceived deficits in information about climate change have been filled but where expected transformations in behavior, based on enlightened self-interest, have not materialized. Answers to this tend to fall into the realm of external and internal factors (**Figure 3**).

One external factor is where there are institutional barriers to forming a change in human behavior. Appropriate changes in behavior are difficult if enabling institutional or physical infrastructure is not in place on a macroscale (e.g., legal and binding international agreements, national policies on energy efficiency, recycling and public transport services, etc.). In other cases, infrastructure may be in place on a macrolevel but have not percolated down into the institutions with which humans interact on a routine basis (e.g., businesses, schools, universities, armed forces, and hospitals). Another factor can be lack of peer support. Changing consumption habits, for example, can be difficult or intimidating if it involves breaking inherited cultural norms and expectations. Another external factor is cost. An individual might wish to choose carbon-efficient options but feels that the cost is prohibitive.

External barriers can also have a negative impact upon individual perceptions about being the locus of control (i.e., do individuals have the power to do anything about a global problem like climate change anyway?). However, there is ambiguity over the interpretation of expressions of powerlessness, as this emotion can also have internal drivers. For example, people who have a strong predisposition to feel that they are agents of change are less likely to accept external barriers passively than those who are more resigned to accepting external constraints (Kollmuss and Agyeman, 2002). Perceptions of powerlessness can also be used as a strategy to deny personal responsibility (Barr et al., 2011a).

Other internal reasons explaining the value-action gap focus upon human cognition. People absorb new information through preexisting cognitive structures. Therefore, human recognition of climate change can sometimes be culturally overdetermined (Moser, 2007). Many people naturally associate climate with weather and are accustomed to seeing the weather as an uncontrollable force of nature. Therefore, there is a cultural propensity for cognitive spillover in the sense that climate change is interpreted as being 'like the weather' (something which individuals cannot possibly control). Evolution has also left Homo sapiens with all-too-human cognitive disabilities when making rational choices about the risks of climate change. Human judgment is colored by emotions that, from an evolutionary perspective, have become hardwired. For good prehistorical reasons, human emotions overdetermine the cognition of risk by prioritizing immediate personal danger. Climate change is a long-term process with almost unfathomable lags between cause and effect. It is incremental and intangible. It also lacks immediacy because its impacts are 'global' and can appear unthreateningly remote. Therefore, climate change may be placed in the 'less-urgent threat' category until the deadline for acting has passed.

Emotions can also contribute to the value-action gap as defense mechanisms. In some cases, individuals may recognize accounts of climate change but filter them out of consciousness to reduce cognitive dissonance (Kollmuss and Agyeman, 2002). According to the theory of cognitive dissonance, humans seek consistency in their beliefs and selectively commit information to memory based on whether it complies with or challenges existing mental frameworks. They also display archetypal fear reactions, namely: fight, flight, or freeze (Moser, 2007). If climate change information stubbornly demands

Figure 3 Information deficit model and possible reasons for 'value-action gap.'

attention (in effect another confrontation), one instinctive reaction is to contemplate putting up a fight. Flight from climate change information can come in many forms that are not always logically consistent: it does not exist; it may exist but we do not know enough yet to act; it does exist but is not a threat; it is a threat but it will not happen to us; anyway it is someone else's responsibility; technological solutions are just around the corner. A freeze response to knowledge of climate change might express itself in the form of emotive fatalism or, as Moser (2007) puts it: 'the capitulatory imagination.'

For these reasons, Moser and others caution that it can be counterproductive to manipulate emotions like fear of climate change. Attempts to evoke fear through media campaigns, for instance, may result in 'maladaptive reactions' unless target audiences feel they have a clear mitigation or adaptation plan and a sense of retaining control. Similar arguments are invoked to claim that trading on guilt can also be misguided. There is a temptation to apply shame or responsibility because guilt has some potential for changing behavior. On the other hand, humans also have a capacity for building immunity to guilt and may experience compassion fatigue, especially if they suspect it is being used manipulatively. There also comes a point where guilt can be a barrier to action if it erodes individuals' sense of identity as morally upright beings.

Another key lesson from sociobehavioral research is that effective communication of climate change requires some knowledge about the characteristics of intended target audience. To this end, social marketing techniques have been identified as a potentially fruitful way of understanding barriers to individual responses to climate change (Barr et al., 2011b). Surveys and focus groups can be used to segment public opinion according to whether individuals are committed or casual environmentalists, partly or completely disengaged, or according to their level of belief that technology will provide solutions to climate change. Thus, rather than treating audiences as an undifferentiated mass, those seeking to stimulate changes in attitudes and behavior can strategically hone climate messages to target specific audiences and deconstruct their particular barriers to behavior change. Public opinion can also arguably be segmented not just in terms of general worldviews and opinions on climate change, but also in terms of sites and practices of consumption. One study by Barr et al. (2011b) revealed that one lifestyle group that professed careful attention to 'climate-friendly' behavior in and around the home found it challenging to carry over similar behaviors when it came to tourism and air travel.

Conclusion

Although ostensibly a natural scientific issue, the social and economic effects of climate change have made it an obvious and important subject of social and behavioral enquiry. Its prominence has persisted despite ebbs and flows in political (and to some extent public) attention to climate change as a result of events like the failure of the 2009 Copenhagen Climate Conference and the external pressures and agendas created by the 2008–09 economic crisis. The multiple intertwinements that exist between the physical processes and effects associated with climate change and key aspects of human society nevertheless assure that climate change will retain a prominent, and quite conceivably preeminent, place in social-scientific and behavioral research in the coming decades.

Climate Change and Global Poverty

Abigail Jones and Joshua Hermias, Washington, DC, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Although the effects of climate change will be felt world over, studies broadly agree that the distribution of impacts will be skewed against the world's poorest countries which have limited capacity to adapt. This differential impact is both a function of geography and of a confluence of economic, social, and political factors. This article highlights projected effects of climate change across a number of key sectors in low-income countries as a forecast across the literature. We conclude with a discussion of key research challenges for the decade of the 2020s.

Climate Change and Global Poverty

Although the effects of climate change will be felt across the entire planet, studies broadly agree that the distribution of negative impacts are skewed toward the world's poorest countries. Climate-related changes to the environment are especially disproportionate near the equatorial belt, an area that mostly comprises low-income countries. Compounding this heterogeneity of environmental effects is the low-income countries' acute vulnerability to climate change. As these countries continue to address long-standing economic, social, and political development needs, their capacity to recover from and adapt to climate change impacts is limited.

Both an individual's and a country's ability to cope with the effects of climate change are fundamentally connected to economic and human development. When faced with rising food or fuel prices, for example, wealthy individuals can cope by dipping into savings; however, for the poorest families, who spend 45–80% of their income on food, rising prices force stark tradeoffs (Banerjee and Duflo, 2011). Similarly, low-income countries often lack sufficient resources and technical capacity to adequately invest in protective infrastructure, social safety nets, and recovery operations, especially when compared to the capacities of high-income countries.

Adverse climate impacts are also expected to threaten positive trends in growth and poverty reduction over the medium and long term. In poorer countries, a 1 °C rise in regional temperature in a given year dampens growth in that year by about 1.3 percentage points, meaning that the adverse effects of climate change will be felt throughout the economies of poor countries for years to come (Dell et al., 2012). This article highlights projected effects across a number of key sectors in the developing world as forecast across the literature, and concludes with a discussion of key research challenges for the coming decade. The impacts discussed come from a diverse body of scholarship that is based on differing assumptions and underlying models. However, before turning to sector-specific impacts, it is important to situate this challenge within the broader frame.

Sustained growth, climate change, and related impacts comprise a complex system that remains a topic of intense scrutiny. A key ingredient to economic growth to date has been carbon-intensive energy. In turn, carbon-intensive activities exacerbate climate change; the impacts of these changes eventually feedback into growth potential. Thus, many observers point to an 'energy-growth puzzle'. Although many pollutants seem to follow the so-called environmental Kuznets curve, rising with income until a certain threshold is met and then declining thereafter, greenhouse gas emissions do not follow this pattern; though emission intensity tends to diminish at high-income levels, emissions rise monotonically with income at every level (Jones et al., 2009).

Increasing access to energy remains an important development imperative to many countries' growth strategy. Today, about 1.3 billion people lack access to electricity (one in five people), while unreliable electricity networks serve another 1 billion people. More than 95% of the energy poor are either in sub-Saharan Africa or developing Asia, while 84% are in rural areas – the same regions that are the most vulnerable to the adverse effects of climate change (International Energy Agency, 2011). At the same time, successfully confronting climate change – the impacts of which are already being felt disproportionately by the poor – will require a global shift toward sustainable energy. Half the world's greenhouse gas emissions come from developing countries, however in 2030, carbon dioxide emissions from non-OECD countries are projected to exceed those from OECD countries by 72%. Because unmanageable climate change risks threaten to reverse development gains, efforts to alleviate energy poverty are sometimes at odds with mitigating climate impacts; sustainable and noncarbon-intensive energy sources are an often-cited alternative for solving portions of the energy-growth puzzle.

Water

Climate change is likely to alter precipitation patterns (Meehl et al., 2007). Already, increased precipitation has been observed in the eastern parts of North America and South America, Northern Europe, and Northern and Central Asia, while drying has been observed in the Sahel, Southern Africa, the Mediterranean, and parts of Southern Asia. Models predict that global warming will affect water availability and demand across the developing world with some regions experiencing increased drought and others experiencing severe flooding as a result. These stresses will present challenges for human health, agricultural productivity, and local infrastructure, with attendant consequences for poverty alleviation and economic growth.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64042-4

Increased water stress is expected across many parts of the developing world with more precipitation in high latitudes and less precipitation in subtropical regions. Throughout Africa, warming is likely to be larger than the global annual mean, which in part will contribute to the complete disappearance of the ice caps of Mount Kilimanjaro by 2020 (Thompson et al., 2002). Between 75 and 250 million people, or 6–20% of the projected population, will be at risk by 2020; another 275–350 million people are expected to join their ranks by 2050 leaving anywhere between 16 and 30% of the continent's population facing water stress from climate change alone (Arnell, 2004). Three degrees of warming may push many African nations beyond the limits of their economically usable, land-based water resources within the next 15 years (Ashton, 2002). In Central and South America, annual mean warming is likely to be above the global mean, leaving between 12 and 81 million people at risk of increased water stress by 2020 and 79–178 million people at risk by 2050 – up to 25% of Latin Americans (Magrin et al., 2007). In Asia, the melting of glaciers due to warming temperatures could seriously affect half a billion people in the Himalaya-Hindu-Kush region and a quarter of a billion people in China who depend on glacial melt for their water supplies. While river runoff will initially increase with glacial melt, over time water supplies will fall as a result of limited ice resources with detrimental effects for downstream agriculture in most countries of South Asia (Cruz et al., 2007).

Climate change will also affect water quality through both direct and indirect effects (Nyong, 2009). The global average sea level rose at an average rate of 1.8 mm a year, over the period 1961 to 2003, however the rate of sea-level rise between 1993 and 2003 was considerably faster, at about 3.1 mm a year (Solomon et al., 2007). As sea levels rise due primarily to ice sheet melt, the coastal regions of Africa, Bangladesh, China, India, and the small island states will see increased salinity in their ground and surface water. Furthermore, years of over-exploiting groundwater will leave it vulnerable to saltwater intrusion in many coastal areas (UNEP, 2007).

Water sustains the livelihoods of society and makes productive economic activity possible. With the hydrological changes anticipated in a warmer world, future water scarcity may put at risk many societies' capacity to feed their growing populations, power industrial development, for example, for thermal power plants, as well as the functioning of natural ecosystems absent innovation and technological change (World Bank, 2012).

Agriculture and Food Security

The impact of climate change on global agricultural activity will have acute affects in the developing world. Seventy-five percent of the world's poor live in rural areas, with 86% of rural people engaged in agriculture-related activities. Agricultural activities are especially important to development because work occurs both in the formal labor market, where individuals are employed as workers, and as a form of self-employment or subsistence activity (World Bank, 2007).

From a macroeconomic perspective, developing countries remain dependent on the farming sector as an engine for growth and development. Agriculture accounts for about 30% of gross domestic product (GDP) in developing economies. The World Bank (2007) estimates, for example, that GDP growth generated in agriculture, on average, is four times more effective in benefiting the poorest half of the world's population than growth generated outside agriculture. However, the performance of the agricultural sector is sensitive to climate change impacts. This sensitivity is especially acute for developing countries, which have less fiscal and technical capacity to adapt to climate impacts yet face some of the more severe projections in terms of agricultural productivity.

Climate change impacts on temperature and rainfall affect a variety of factors important to agricultural environments and ecosystems: the location and area of land suitable for farming, the selection of crop varieties that are viable, and the length and productivity of the growing season. These several factors result in a wide variety of predicted outcomes. Global warming is predicted to favorably impact agricultural environments in current temperate and even arctic areas of the Northern Hemisphere; rising temperatures and better rainfall patterns will lengthen growing seasons in some areas and open new lands to farming in other areas. China, for example, may experience gains in cereal outputs of more than 20%. Climate change models also suggest, however, negative impacts on agricultural activity, especially for many tropical and subtropical developing countries. In these areas, the area of land suitable for farming decreases amid rising temperatures and increased water scarcity. Under these conditions, it is thought that wheat crops, for example, will completely collapse in sub-Saharan Africa. At the global level, the net impact of climate change on agricultural GDP from projection baselines are small, ranging between −1.5 and 2.6%; however, for most developing countries, the impact is certainly negative, with Africa seeing the largest losses, ranging between −2 and −9% of GDP (Fischer et al., 2002).

Agricultural yields may also be impacted by climate change through secondary affects. Warmer environments are often more hospitable to crop-destroying pests and plant disease. Erratic and volatile weather patterns make it difficult for farmers to plan – and at the most extreme, severe storms, floods, or droughts can directly damage crops.

Agricultural activities also include aquaculture and livestock. Like plant crops, these activities are also sensitive to environmental conditions and impacts will be heterogeneous. Temperature increases of 1.5 °C, for example, can cause fish stocks to shrink or move to different locations like plant crops – some areas will gain and some areas will lose (McLean et al., 2001).

From a human development perspective, agriculture also remains vitally important to the poor, who both depend on agricultural employment for wages as well as agricultural outputs for food security. While agricultural work can be part of a robust livelihood, there is significant overlap between those who are poor and those who are engaged in agriculture. In Banerjee and Duflo's (2011) 18-country data set, the percentage of rural households living in extreme poverty with a household member working in agriculture ranged from 0.6% in Ghana to 93% in Cote d'Ivoire. Households also reported a wide range of self-employment in the agricultural sector: 32% of rural households living in extreme poverty in Mexico report

that at least one household member is self-employed in agriculture, while this figure in Bangladesh was roughly 92%.

Health

Climate change will pose additional challenges for human health and delivery systems across the developing world with adverse consequences for development and economic growth, as healthy populations are more productive and resilient in the face of adverse shocks. It will do so through four primary channels including: direct weather events, for instance, heat waves and severe storms, changed microclimates that alter the range of diseases, altered precipitation and drought that vary food production, and increased air pollutants and airborne allergens. Already, 9 million children under 5 die each year across the developing world from preventable diseases such as diarrhea and malaria (Banerjee and Duflo, 2011). While mortality attributable to climate change accounted for only 0.3% of global deaths and 0.4% of disability-adjusted life years lost (a measure of the total health burden) in 2000, further warming is projected to aggravate these burdens, complicating household decision-making about everything from education to investment and adding pressures to nations' health infrastructure and budgets (Ebi, 2009).

Direct weather events will pose new challenges for health systems across the developing world. Tropical cyclones, storm surges, heat stress, flooding, and drought will directly cause injuries and mortalities, as well as displace affected populations. Migration resulting from climatic threats provides an avenue for the spread of diseases, while natural disasters are expected to take a heavy toll on the mental health of the people involved (Hajat et al., 2003).

Climate change is projected to alter the range of vector (tick, rodent) and waterborne diseases as precipitation patterns, temperatures, and humidity change, including malaria and dengue fever, increasing the absolute number of people at risk. Estimates suggest by 2050, over 200 million people will be at risk of contracting malaria due to climate change pushing the total figure to roughly 5.2 billion. In some areas in South America, sub-Saharan Africa, and Asia, the malaria transmission rate is projected to be 50% higher (Béguin et al., 2011).

Increasing temperatures and decreasing water availability due to climate change may increase burdens of diarrheal and other infectious diseases in many parts of the developing world. This is especially true in some small island developing states (Singh et al., 2001), regions of sub-Saharan Africa, and in Southeast Asia (McMichael et al., 2004). Widespread contraction of diarrhea could exacerbate malnutrition, compromising peoples' ability to work and attend school.

New air pollutants and airborne allergens will increase across regions experiencing more frequent forest fires, including some countries in Latin America. Forest fires have been associated with an increased risk of respiratory diseases and breathing problems, which could adversely affect the labor force in effected countries (WHO, 2000).

The extent of these impacts will depend not only on the magnitude and rate of climate change, but also on factors including wealth, education, the status of each nation's public health infrastructure, the provision and scope of medical care, access to adequate nutrition, safe water and sanitation, and the timeliness and effectiveness of interventions to address the risks of climate change (Ebi, 2009). It will also depend on whether current barriers to the adoption of cheap, effective, and readily available treatments (for instance, bed nets to curb malaria transmission) can be overcome in the near term (Banerjee and Duflo, 2011).

Coastal Areas and Settlements

There has been sustained population growth in coastal areas over the past two decades. Currently, 40% of the world's population lives 100 km from the sea; 73% of this population live in developing countries.

Coastal populations have long been centers of poverty. Campbell et al. (2006) posit that the poor are attracted to the coast because of access to common-pool resources like fish and because of a diversity of livelihoods that are often eschewed by more privileged groups. Of course, these livelihoods tend to be more fragile, depending on hard labor and risk taking, as well as exogenous factors commonly associated with natural resources. Even apart from climate change impacts, for example, fishing livelihoods are increasingly vulnerable to shocks from pollution, competition from global markets, and overfishing.

The most profound impact of climate change on coastal areas is sea-level rise. Global warming leads to higher sea level from melting ice caps and glaciers, as well as through the thermal expansion of water as it becomes warmer. Projecting future sea-level rise remains a considerable challenge for the scientific community, with various methodologies producing a large range of possibilities: at a 4 °C warming by 2012, the mean estimate ranges between 47 and 96 cm of sea-level rise, depending on methodology (World Bank, 2012). Absent massive infrastructure investments like seawalls, as sea levels rise, low-lying coastal areas will become inundated with water leading to increased flooding, erosion, and, in the most extreme cases, submersion of coastlands and mangrove forests. These outcomes can lead to population displacement, loss of life and property, contamination of groundwater, and destruction of infrastructure and natural features – all of which impact the poor both directly and through general disturbances to economic activities they may depend on.

Sea-level changes, like many climate impacts, are not evenly distributed. Numerous factors including sea floor morphology, Earth's rotation and gravitational forces, and air and water currents affect the distribution of ocean water. Low-lying tropical areas are more vulnerable, for example, as sea-level rise may be 20% higher in this region than near the poles (World Bank, 2012). Similarly, the geography of small islands leave them acutely exposed to extreme flooding, salinization of drinking water, and changes in surrounding ecosystems.

The increased levels of atmospheric carbon dioxide associated with global warming projections also lead to projections of ocean acidification, as CO_2 dissolves into water. Ocean acidification can exacerbate coastal flooding because it can lead to the destruction of protective barrier reefs. The loss of reefs and changing habitat environments may also devastate fish

populations and tourism, and thus threaten coastal livelihoods (World Bank, 2012).

Natural Ecosystems and Biodiversity

Almost one-third of the wealth of low-income nations is in their 'natural capital' – their rivers, forests, grasslands, and oceans (World Bank, 2006). Yet the value of this capital per person is lower in developing nations than in high-income countries, which are far less forested in absolute terms (World Bank, 2006). Natural ecosystems are equally important for human development, as forest resources directly contribute to the livelihoods of almost 90% of the extreme poor in developing nations (World Bank, 2003). However, recent assessments have identified significant effects that climate change will have on terrestrial ecosystems.

Terrestrial systems will be affected to varying degrees across and within regions of the developing world. In Latin America, numerous tree species will likely be lost. By mid-century, 24% of 138 tree species in the savannas of central Brazil will be threatened with extinction, while by the century's end, 34% of 69 tree plant species could become extinct in Amazonia. Up to 40% of the Amazonian forests could react drastically to even a slight reduction in precipitation with attendant consequences for tropical vegetation, hydrology, and the climate system across South America (Magrin et al., 2007). In Africa, forest productivity will likely decline (UNEP, 2007) and between 25 and 42% of plant species could lose all suitable range by 2085 (World Bank, 2012). In Asia, up to 50% of the region's total biodiversity could be at risk, with projections showing that 105 to 1522 plant species in China alone could become extinct by the end of the century (Cruz et al., 2007).

These degraded and lost sources of natural capital will place the poor at further risk, as forests provide a natural defense against flooding and drought, and can improve water quality by filtering out harmful pollutants and pathogens. Forests also provide other less tangible benefits to poor communities. For example, in the Amazon River Basin indigenous peoples consider forests to be essential to their cultures, traditional livelihoods, and religious practices (Jones et al., 2009).

Disasters

A warmer world is projected to be a more violent one, with more frequent and intense extreme weather events potentially setting back economic and human development gains. Between 1990 and 1999, an estimated 188 million people a year were affected by extreme weather, droughts, floods, and other such disasters, six times more than the 31 million annually affected by armed conflict. Immense storms, like the massive cyclone that destroyed much of coastal Burma in May 2008, uproot millions of people from their homes. Some estimates suggest that the number of environmental migrants and refugees could grow by tens of millions in the coming decades. In addition to direct displacement, disaster victims often end up in makeshift camps or dysfunctional communities plagued by crime and violence (Jones et al., 2009).

Substantial scientific evidence has begun to link recent, extreme weather events to global warming with medium to high levels of confidence. In 2011, record breaking heat and drought in the United States induced damages estimated between US$6 and US$8 billion and proved that developed countries are also vulnerable to extreme weather. The European heat wave of 2003 claimed more than 70 000 lives (World Bank, 2012). Yet in the future, poor countries and communities, particularly in Africa and Asia, will face the gravest risks. Their vulnerability is both a function of their geography, as places near the equator and the poles and along seacoasts are likely to experience the most pronounced effects of climate changes, and of weak institutions. Developed economies have greater capacity to adapt and absorb displaced populations (CAN Corporation, 2007), while states with weak institutions stand a higher risk of being destabilized by extreme weather events.

Conclusion

Climate change and development are fundamentally linked. How nations grow affects the climate, yet whether nations grow determines how economies and citizens are equipped to cope with climate impacts. If countries develop along traditional, carbon-intensive energy pathways, climate impacts will mount, all else equal. However, the ability to develop robust economies, political systems, and societies is also critical in determining local, regional, and global responses to climate change: adverse climate impacts will be magnified if developing countries are too poor to invest in adaptive measures and infrastructure or weather, the global economic consequences of mitigating climate change.

In turn, global warming has enormous implications for the lives of the millions living on less than a dollar a day across the developing world. What is in store for the world's poorest people as global mean temperature rises depend in part how much the world is able to abate greenhouse gas emissions. Yet many known adverse effects, including sea-level rise, heat waves, and rainfall variation are already underway. Although quantifying the full scale of consequences on livelihoods is not yet possible, it is clear that climate change has the potential to seriously undermine poverty alleviation in many regions. Both past trends and future projections show that adverse climate impacts have a negative effect on economic growth in developing countries (World Bank, 2012).

Future researchers will need to grapple with the many feedback loops and interactive effects between the sectors as impacts mount, greenhouse gas emissions continue to accumulate, and populations grow across the developing world. For instance, greater water scarcity in regions experiencing decreased annual precipitation will have significant effects on national economies through a number of channels including health and agriculture. However, greater water insecurity could also compromise national energy systems, as they require water to power generation and transmission. The dynamic effects between sectors have not yet been fully modeled, and such work would help provide a clearer understanding of how both low-income and high-income economies will need to adapt to flourish in a warmer world.

Climate Change and the Media

Mike S Schäfer, Universität Zürich, Institut für Publizistikwissenschaft und Medienforschung, Zürich, Switzerland

Abstract

Media communication – and the coverage of mass media such as TV, radio, newspapers, or the Internet in particular – is an important source for people's awareness of, and knowledge about, anthropogenic climate change. Accordingly, many scholars have analyzed the emergence, characteristics, uses, and effects of mediated communication about climate change in recent years. This article reviews the respective field, presents its major findings, and outlines future directions for research.

The Relevance of the Media in Climate Change Communication

Climate change, compared to many other issues, is an 'unobtrusive' topic. This is because the climate and its past, current, or future developments are not easily observable first hand. The term 'climate' refers to statistical averages of weather indicators, such as temperatures, precipitation, wind, and so on. To speak of 'climate,' these indicators have to be monitored and described on large scales both in terms of space and time. The World Meteorological Organization, for example, proposes to speak of 'climate' when referring to average weather over at least 30 years. Spatially, 'climates' are usually described for entire countries, continents, hemispheres, or the whole world. Such dimensions lie far beyond most people's life-worlds and biographical horizons. In addition, the main anthropogenic causes of climate change – greenhouse gas emissions – remain invisible.

A second reason for the issue's unobtrusiveness is its complexity. The climate and its changes are observed and (re)constructed primarily by scientists, whose results are rather complex and difficult to understand for many people. This is due, among other factors, to the growing number of disciplines participating in climate science. Each comes with its own kinds of data, measures, models, and heuristics, which results in climate models including more and more variables and interrelations between these. Moreover, the findings of climate science, as those of any other science, are not unanimously agreed upon. Although a consensus seems to exist within the respective scientific community about the basic features and causes of anthropogenic climate change, dissent, and uncertainty can be found in many details.

Thirdly, climate change is also an unobtrusive issue because its social effects and the measures to mitigate them are debated, complex, and, at times, difficult to understand: A lot of the consequences of climate change, and most likely the more severe ones, are not occurring here and now. They will appear in the future and affect countries in the 'Global South' more than those in North America or Western Europe. In addition, stakeholders advocate different actions that are often based on elaborate, difficult to understand rationales and justifications. The most important strand of current climate politics involves international efforts at 'mitigation,' that is, a reduction of greenhouse gas emissions in developed countries, in particular, constituting a political process that is far removed from people's life-worlds.

As a result, the causes and consequences of climate change and its implications are not directly and easily perceivable, and what most people know about them stems from media communication. The mass media – means of communication that distribute content such as text, pictures, and sound to an anonymous and spatially diverse public via technical means, such as newspapers, TV, or radio – are particularly relevant in this respect. Surveys in the US, the UK, Australia, and Germany show that mass media – particularly television, followed by newspapers and, increasingly, the Internet – are the most important sources from which people draw information about climate change. These studies also show mass media to be more important than people's interpersonal communication with family members and friends, as well as workshops and school classes. Accordingly, they are "important arenas and important agents in the production, reproduction, and transformation of the meaning" of climate change (Carvalho, 2010: 172).

Overview of the Research Field

The outlined importance of mass media communication on climate change has long been acknowledged by the scientific community. A number of introductory texts into the field are available, such as Moser's (2010) historical overview of climate change communication that spans mass media as well as other kinds of communication. Carvalho's (2010) description of the politics of climate change communication, Schäfer's (2012) overview of online communication about the issue O'Neill et al. 's (2013) review of visual communication about climate change, and Anderson's (2009) or Olausson and Berglez's (2014) programmatic formulation of a future research agenda are further examples.

Taken together as a whole, the research field reveals a number of specifics. A recent *meta*-analysis of some 130 relevant publications shows the growth of the field (Schäfer and Schlichting, 2014): After only a few analyses were published in the 1980s and 1990s, research activity increased and remained on a moderate level until the mid-2000s, when annual publication numbers rose considerably. Today, analyses of media representations of climate change constitute a lively and growing field.

This growth is accompanied by a diversification of research approaches and objects. A relatively large number of earlier single-country case studies (e.g., Boykoff, 2008; Gavin et al., 2011) have increasingly been supplemented by comparative

and longitudinal research. The theoretical foundations of the respective studies range from politically oriented agenda-setting approaches to critical discourse analysis and adopt quantitative, qualitative, and mixed method research designs.

In spite of this diversification, however, the research field is still strongly focused on a small number of countries and media: European and North American countries have received by far the largest share of research attention and continuously do so. Asian, African, and Latin American countries, many of whom are strongly affected by the outcomes of climate change, have not often been analyzed (Schäfer and Schlichting, 2014). In addition, most studies focus on print media, particularly broadsheet newspapers. Even though the number of analyses taking up online and social media is increasing, other media are largely neglected. The importance of television as a source of information about climate change, in particular, has not led to an equally strong amount of scholarly attention for climate change portrayals on TV.

Furthermore, not all steps of the communication process are taken up equally. Most studies focus on the media presentation of climate change, i.e., on how much attention media devote to the issue, or how they evaluate and frame it. In contrast, analyses of production processes, i.e., how different stakeholders try to position themselves in media coverage and on media consumption and its effects are less common.

The following article will focus on these subdimensions. It will organize the literature into three distinct sections: agenda-building efforts related to climate change, the role of journalists and the characteristics of the respective media representations, and their uses and effects.

Stakeholder Communication about Climate Change

The existence of climate change itself, its extent and urgency, as well as the appropriate responses and measures toward it are "deeply contested[, with] considerable competition among (and between) scientists, industry, policymakers and non-governmental organizations (NGOs), each of whom is likely to be actively seeking to establish their particular perspectives on the issues" (Anderson, 2009: 166). Using different kinds of strategic communication, these stakeholders often aim for media representation because media are the main forum for public debates in modern societies and important sources for information about climate change for many people. Therefore, stakeholders try to position themselves in the media in order to be seen as relevant and viable actors in the field, and to inject their positions and views into coverage in order to influence the societal perceptions of climate change and the subsequent decisions about paths of action.

A considerable number of studies from political science, sociology, communications, and public relations have analyzed these efforts using structuration theory, agenda-building theory, theories of the public sphere, or social movement theories (for overviews see Hall and Taplin, 2007; McCright and Dunlap, 2003). They have shown that many concerned parties exist in the case of climate change, which devote large amounts of monetary, personal, cultural, and/or symbolic resources to the issue. The strategic communication of these stakeholders can be organized in different 'frames,' i.e., ways of interpreting climate change from a certain perspective that correspond with preferences for specific solutions (Table 1).

Anthropogenic Climate Change as a Global Problem

The first frame, which already emerged in the early 1990s and has been powerful ever since, emphasizes the existence of anthropogenic climate change, and advocates various measures to fight it. Its proponents consist of renowned individual scientists such as James Hansen (US), Nicholas Stern (UK), and Hans Joachim Schellnhuber (GER), prominent activists like Al Gore, hybrid scientific/political organizations such as the United Nations' Framework Convention for Climate Change's (UNFCCC) Intergovernmental Panel on Climate Change (IPCC), large international environmental NGOs such as Greenpeace or the World Wildlife Fund, and, in many countries, green parties. These stakeholders use their considerable resources to argue that the "warming of the climate system is unequivocal, as is now evident," and "very likely due to the observed increase in anthropogenic [greenhouse gases]" (IPCC). It is further emphasized that these developments lead to more extreme weather, intensify resource shortages, and are "already harming people and ecosystems" (Greenpeace). Therefore, the need for action to counteract climate change is emphasized, such as the '2-degree goal' to limit global warming at 2 °C compared to preindustrial levels.

Scientific Uncertainty

In the mid-1990s, and particularly among representatives of the US and Australian oil and automobile industries, a counterframe to the abovementioned perspective emerged that has also been used in other science-related public debates, for example, around the effects of smoking and secondhand smoking or genetic engineering: the 'scientific uncertainty' frame. It was sponsored by international corporations like Shell or Elf as well as their representatives such as the 'Global Climate Coalition,' conservative think tanks, and various administrations and political parties (especially in the US and in Australia). The frame was less prominent in Europe and other countries and has lost importance since the 2000s. The frame argues that while global warming may exist, "Scientists do not agree on man's effect on the climate" (Citizens for a Sound Economy Foundation). Those scientists who argue otherwise are portrayed as 'alarmists,' and their work is discredited as 'junk' or 'pseudo' science that has a 'political purpose' (Global Climate Coalition). If anything, a proper response to the alleged state of affairs would be more research, but any political regulation is rejected as being premature.

Economic Development

A third frame emerged in the wake of negotiations leading up to the Kyoto Protocol. It accepts global warming as existent and human activity as its major cause, but stresses the high economic costs of action. "We are now trying to be more positive with the science, while still pointing to the high cost of precipitate action" (Ford), which might "cost American families billions of dollars and millions of jobs" (Global Climate Coalition) and "damage competitiveness" (Australian Industry

Table 1 Frames of climate change and their sponsors

Frame	*Anthropogenic climate change as a global problem*	*Scientific uncertainty*	*Economic development*	*Ecological modernization*
Central organizing idea	Scientific evidence shows climate change exists and is man-made; action is needed	Scientific evidence about climate change is inconclusive; therefore, action would be hasty	Climate change does exist, but measures will seriously hamper (domestic) economic development	Technological development is key to fighting climate change, industry, and developed countries as pioneers
Framing devices	Scientific evidence points to 'climate catastrophe'; atmosphere as global 'common good'; historical responsibility of developed countries; global 'climate justice'	Climate science as 'alarmist' and 'junk science'; its background as a political complot; climate change is 'a theory, not a fact'	Climate change regulation leads to 'crippled economy' and 'restricted lifestyle' as well as a 'transfer of wealth'	Corporations acknowledge 'responsibility,' reframe them as 'business opportunities' for 'bridging technologies'; 'Ecoimagination'
Main frame sponsors	Prominent individual scientists and activists, scientific institutions and organizations, IPCC, environmental NGOs, green parties	Fossil fuel, coal, automotive, and electric utilities industry, their associations; think tanks, conservative politicians, especially in the US	US fossil fuel, coal and automotive industry, Australian coal industry, conservative politicians	European multinational corporations, later adopted by many industry sectors in many world regions
Occurrence	Emerged in 1990s and is still widely used	Early to mid-1990s, relatively widespread geographically, most strongly present in Anglo-Saxon world	From Kyoto negotiations in 1997 to early 2000s	Started around Kyoto negotiations, first in Europe; strong in many countries since mid-2000s

NGO, non-governmental organizations; IPCC, intergovernmental panel on climate change.

Greenhouse Network). Accordingly, it is argued that political measures have to take this into account, and that the responsibility for tackling climate change cannot solely lie on industrialized, developed countries. To be as effective as possible, it calls for a global effort that included countries like China, India, Brazil, and others. Accordingly, international agreements are rejected as long as they do not include all countries. This frame is especially prominent among political and economic factors from developed countries, especially from countries with a strongly fossil-dependent economy like Australia or Norway, but it also includes the US.

Ecological Modernization

The fourth frame acknowledges climate change as "the single biggest environmental challenge facing the planet" (Hong Kong Shanghai Bank of China), but focuses on technological development as the key to fighting climate change and describes industry actors and developed countries as pioneering this development. It highlights the potential of an ecological modernization to create jobs and national welfare. Accordingly, the frame resonated not only among industry representatives from BP, Shell, other companies, and conservative politicians, but also among trade unions and NGOs, in civil society and among liberal-to-left politicians like the Blair administration in the UK.

In some variation, these frames are prevalent among many stakeholders and in many societies. In some countries, particularly Anglo-Saxon ones, stakeholders fall into two fiercely competing camps of climate change: proponents and skeptics. Whereas in countries like Germany, the Netherlands or India, the different frames and their sponsors are found in a less conflictive situation.

'Climate Journalists' and Their Role

Agenda-building efforts directed at the media are not always, and not equally, successful. Publishing houses and journalists play important roles as an intermediaries in this respect. Being seen by journalism theory as 'gatekeepers' of the news flow, they ultimately decide which topics, stakeholders, and perspectives are represented in the media. Accordingly, the role of journalists in climate change communication has received some scholarly interest (for overviews see Bodker and Neverla, 2013; Brüggemann and Engesser, 2014). Most of these studies are content analyses that measure journalistic output and extrapolate information about the journalists from there, while surveys among journalists and in-depth ethnographic studies in newsrooms are largely missing.

Who 'Climate Journalists' Are

Even though little is known about the sociodemographic characteristics and attitudes of 'climate journalists,' studies have shown that they are a diverse group of professionals and

that their positions within the media differ strongly. As climate change is a cross-sectional topic that includes scientific as well as political, economic, cultural, and other facets, the issue is taken up by numerous media desks and their journalists. As a result, most journalists writing about climate change are not monothematic experts on this issue. Still, 'climate journalists' seem to have become relatively knowledgeable about the issue over time. While an early US journalist survey showed considerable gaps in their knowledge about climate change, later studies came to different results and documented that journalists' (average) knowledge about the issue is better than that of decision-makers, NGO representatives and others. Moreover, recent findings indicate that most 'climate journalists' are in line with the IPCC view on climate change.

How 'Climate Journalists' Work

Some aspects of climate journalists' work differ strongly from country to country. The sources they tend to use, for example, have been shown to differ considerably according to varying national cultures of journalism – in countries such as Germany and India, scientists are the major sources of climate change coverage, whereas in developing countries media and news agencies from other parts of the world and domestic political elites seem to be more important. Other aspects of journalists' work seem to be rather stable across countries: journalists' working routines consist, among other things, of finding newsworthy topics and highlighting their newsworthiness in their coverage, while adhering to general journalistic norms such as thoroughly researching information and providing a balanced account of an issue to the readers. It has been shown that these general characteristics also apply when journalists cover climate change, but that they sometimes lead to problematic results. On the one side, because the unobtrusive and complex issue of climate change does not cater well to news values, journalists have to find and emphasize its newsworthy aspects in order to cover it. Therefore, they occasionally tend to play down or omit uncertainties connected to scientific information to comply with the news value of 'unambiguity'; or to exaggerate the expected negative outcomes of climate change to comply with the 'negativity' news value. Accordingly, newspaper headlines like "Our Earth is Dying" (German tabloid 'Bild,' 3 February 2007) or, in turn, "Climate Hysteria is a Scam" (Australia's Narrogin Observer, 30 June 2010) have been criticized as being sensationalist and biased. On the other side, established journalistic norms have been shown to be counterproductive at times when covering climate change. The prime example is Boykoff's 'balance as bias' thesis, which argues that the norm of balanced reporting led to a coverage in US media in the 1990s where a minority of climate skeptics was portrayed as being equally important as the (large majority of) proponents of anthropogenic climate change (cf. Boykoff, 2011: esp. 99ff.).

Media Representations of Climate Change

Analyses of media representations of climate change are most prominent in the respective literature, mostly coming from communication and political sciences as well as sociology. These studies cover a large number of different countries – even though still primarily from the Western world – different media outlets, many years, and several facets of climate change. Their main findings are discussed in the following sections.

Climate Change Is a Relevant Media Issue Worldwide

Many studies have focused on the amount of attention media devote to climate change. They show that the issue is a relevant topic in many countries on all continents, outnumbering other hotly debated science issues like stem cell research or genome sequencing. They also demonstrate that media attention for climate change has risen considerably in many countries since the mid-2000s (Schmidt et al., 2014; see **Figure 1**).

Media Coverage Is Event-Driven

In addition, studies have shown that media attention for climate change, as for many other issues as well, strongly fluctuates over time and that it peaks around specific events (Schmidt et al., 2014). Some of these are weather events, particularly extreme weather; coverage about climate change peaked around Hurricane Katrina, the 'flood of the century' in Germany and the heat waves in Europe. Journalists, looking for newsworthy angles of climate change and visible manifestations of the invisible phenomenon, occasionally interpret such events as symptoms for climate change, even though these claims often lack a scientific basis. Other events triggering climate change coverage are sociopolitical ones. Particularly influential are the proceedings of international climate politics, namely the Conferences of the Parties to the UNFCCC process, where international climate politics is debated by high-ranking politicians, and where numerous large NGOs provide additional interpretations and photo ops for journalists. These high-profile political events occur annually, can be prepared for, and systematically focus large amounts of media coverage on climate change and climate politics. But media attention for climate change has also been triggered by the recurring releases of the IPCC Assessment Reports or the Stern Review on the economic impacts of climate change, as well as by cultural events such as the 'Live Earth' concerts and movies like 'An Inconvenient Truth' or 'The Day after Tomorrow' (Schäfer et al., 2014).

Coverage Has Moved from the Science of Climate Change to Its Societal Impacts

Longitudinal content analyses in various countries demonstrate that the placement of climate change in media coverage has changed over time. While it was mostly dealt with on the science pages (or segments) in the early 1990s, the issue moved from being a primarily scientific issue into other sections of the media, most notably to politics and the economy. This is a symptom of a changing focus – a 'societal turn' – in climate change coverage. While the scientific basis of climate change is still being reported upon at times (and, especially in Anglo-Saxon countries, sometimes debated; see Painter and Ashe, 2012), its relative importance has decreased, while climate change has increasingly become a political, economic, and social issue. Aspects like the political efforts toward a global

Figure 1 Media attention for climate change in 27 countries worldwide. For each country, one or two leading print media representing different political positions were chosen for analysis. Leading print media were defined as national media with a high circulation, being published daily and widely regarded as high-quality papers. The final sample of the analysis contained 153 261 articles. Percentages indicate the amount of articles dealing with climate change in relation to all articles published in the analyzed newspapers per month; 1996–2010; gaps in graphs are due to missing data. Source: Schmidt et al., 2013.

treaty on emissions reductions, the costs of moving toward low-carbon societies for national economies, or the humanitarian and security implications connected to potentially intensifying resource conflicts and climate-induced migration, are increasingly taking center stage when media cover climate change.

The Content of Climate Change Coverage Differs Considerably from Country to Country

The increased focus of climate change coverage on societal impacts also seems to come with an increasing 'domestication' of the issue. While the timing and, to some extent, the occasions of coverage are still quite similar internationally – particularly among Western European and North American countries – the content of coverage often differs considerably. While coverage in the Netherlands, for example, focuses more on technical solutions in line with the described 'ecological modernization' frame, Swedish media emphasize moral and ecological aspects to a larger extent. German media display rather 'warmist' standpoints similar to the 'anthropogenic climate change as a global roblem' frame, whereas media coverage in the US and Australia is stronger polarized between skeptics and warmists who devote more attention to the 'scientific uncertainty' frame. In countries beyond the Western world, such as India or Bangladesh, postcolonial arguments can be found, which interpret climate change as mainly of Western concern (e.g., Billett, 2010).

Uses and Effects of Media Representations of Climate Change

Compared to the analyses of media representations of climate change themselves – which are often justified with their alleged effects on people's issue awareness, knowledge, or behavior – their actual uses and effects have received less scholarly attention (cf Taddicken, 2013). Furthermore, scholarship on these issues has many gaps: Studies tend to focus on cognitive effects, but not on affective and other effects; on information-oriented formats and not on entertaining or fictional ones; on print media and not on TV (which has been shown to have the strongest effects in general and to be the main source of people's information about climate change); on individual level effects and not on meso (institutional) and macro (societal) effects; and on the general public and not on special audiences such as scientists, politicians, or journalists. In addition, the results of the few existing studies paint an unclear, incoherent, and sometimes contradictory picture. Nevertheless, a number of recurring results can be extracted.

Mass Media Are Important and Trusted Sources for Climate Change Information

Regarding the uses of media representations of climate change, it has been shown repeatedly that mass media – particularly television and newspapers, but increasingly the Internet as well – are the most important sources for people's information about climate change. Furthermore, mass media also seem to be credible sources, whom people trust more on the issue than, for example, family and friends. Beyond these rather basic facts, however, little is known about uses and reception processes. The social contexts in which users engage with climate-related media content, their motivations, and gratifications as well as their interpretations of the content have not yet been taken up properly. Motivational theories like uses-and-gratifications and theories of interpersonal communication and information diffusion could be useful to shed light on these facets.

Agenda-Setting Effects on the Audience's Issue Awareness Exist

Studies on the effects of media representations of climate change have mainly focused on individual level effects on people's problem awareness, their level of information, and their willingness to act, i.e., on potential first-level agenda-setting effects and on persuasion. They have demonstrated that the amount of climate change representations that people encounter in mass media is linked to their awareness of the issue, pointing toward an agenda-setting effect. This result has mainly been established through surveys of people's self-assessed media use, which are rarely supplemented with analyses of actual media content or use. Future studies should take these factors into account, and also aim to distinguish the specific contribution of different media with regards to agenda setting.

Mass Media Use Increases Knowledge about Climate Change

Cognitive effects of media representations of climate change have also been repeatedly shown. People acquire information about the issue from the media and learn something about it. This includes factual information about the phenomenon itself – the extent and causes of climate change – as well as potential solutions and options for (individual) action (Stamm et al., 2000; Taddicken, 2013). These processes of information acquisition have been well established for cases in which people turn to media specifically for information about climate change. Their existence and extent is less certain for general, unspecific media use, i.e., in cases where people use media habitually and come across climate change information involuntarily.

Behavioral Effects Are Less Clear

The existence of media effects on climate change-related behavior has not yet been established. Studies have found effects of media use on people's information-seeking; those using media and learning from them are more likely to search for more information about climate change in the future (Zhao, 2009). Regarding climate-related behavior and action, however, only some weak media effects have been found, and in practically all cases refer to behavioral intentions rather than actual behavior. Even in these cases, the evidence is mixed: whereas effects could be shown for the intention to engage in 'societally relevant activities,' no media influence could be shown for self-reported investment decisions or lifestyle changes (Arlt et al., 2011). Therefore, more robust studies in longitudinal behavioral effects are necessary.

Outlook

While media portrayals of climate change have been taken up in many studies, scholarship still has many gaps. Analyses of the production, presentation, and consumption of these media portrayals need to be balanced better in the future, with a particular emphasis on the uses and effects of media portrayals of climate change. More studies on media uses and effects could also help assess, and maybe answer, normative calls for social sciences to play a role in the transition toward low-carbon societies. In order to do so, the objects of analysis, namely the countries and media, which are analyzed should be more diverse, with more studies taking up non-Western countries and audiovisual and online media. As climate change is a transnational phenomenon affecting countries around the world, it would also be worthwhile to engage in more comparative research in order to better understand the (potentially) varying perspectives on the issue, and to look for a potential transnationalization or globalization of the respective debates.

Climate Change: Economics

Gary W Yohe, Wesleyan University, Middletown, CT, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

There are two sides to the economics of climate change – the economics of the economic damages, risks, and opportunities associated with the impacts of climate and the economics of the benefits and costs of mitigation. The benefits of mitigation are generally estimated as net damages that can be avoided or delayed by actions designed to reduce emissions of greenhouse gases of all kinds. All of these calculations are uncertain given our inability to understand fully the science of, to comprehend fully the links between global change and local impacts, to translate rigorously impacts into economic consequences that account adequately for adaptation, and the necessity to look many decades into the future. This article reports briefly in successive sections on the economic costs associated with climate change and the economic costs of mitigation, and it concludes with some coverage of caveats and open research questions as of the fall of 2013.

There are, fundamentally, two sides to the economics of climate change – the economics of the economic damages of the impacts of climate change (most appropriately calculated in terms of residual damages after adaptation, but including the cost of adaptation) and the economics of the benefits and costs of mitigation (most appropriately calibrated in terms of the net benefits from reduced damages and the cost of mitigation polices taking account of the design and implementation of those policies); that is, the benefits of mitigation are generally estimated as net damages that can be avoided or delayed by actions designed to reduce emissions of greenhouse gases of all kinds (carbon dioxide, methane, fluorocarbons, black carbon, etc.).

Despite years of concentrated work around the world, all of these calculations are highly uncertain given our inability to understand fully the science of change (the uncertain link between cumulative emissions and changes in temperature), to comprehend fully the links between global change and local impacts, to translate impacts into economic consequences that account adequately for adaptation, and the necessity to look many decades into the future. Perhaps most importantly, these calculations are complicated by the imperfections of economic and social institutions that make assumptions that support estimates in a first best world tenuous at best – except that first-best estimates indicate what could be accomplished if everything worked perfectly. First-best analyses therefore play the same role in the climate change arena as much as standard economic analyses of this or that conducted under the assumption that all markets are perfectly competitive and all negative (or positive) externalities are internalized (see Ebi and Yohe, 2013)

The Economic Cost of Climate Change Impacts

Estimates of the economic damages from climate change have been reported in three different ways. In the first, damages were computed as a percent of gross domestic product (GDP) for a specified rise in global mean temperature. The second tracked damages along specific scenarios that define future socioeconomic and climatic conditions and reports their present value. The third built on a marginality concept called the social cost of carbon (SCC) – estimates of the discounted damages estimated to be attributable to an extra ton of carbon emissions. Researchers calculate SCC by summing the discounted value of extra damage caused each year for as long as it remains in the atmosphere – a process, which requires a model of atmospheric residence time in addition to a sophisticated economic model. The results of the second two approaches are highly dependent not only on scientific parameters like climate sensitivity (the warming associated with a doubling of atmospheric concentrations from preindustrial levels) and atmospheric residence time, but also on assumptions about how to discount the future, how to reflect attitudes toward risk, and how to incorporate attitudes toward income inequality across the globe.

The history of damage estimates begins with the first of these approaches. In 1996, the Intergovernmental Panel on Climate Change (IPCC) reported preliminary estimates of the annual economic impact of a doubling of concentrations of greenhouse gases (~550 ppmv) and an associated 2.5 °C increase in global mean temperature (IPCC, 1996). The estimates reported for the United States, for example, ranged from 1 to 2.5% of anticipated GDP in 2065, respectively (see Nordhaus, 1991 and Titus (1992), for example). For developed countries more generally, damage estimates for the same time period on the order of 1% of GDP were also reported, but larger percentages were projected for developing countries. As a result, global mean damages were thought to lie in the range of 1.5–3.5% of global GDP. The year 2065 was chosen as a benchmark because that was when the specified doubling of concentrations was anticipated to occur. It is interesting to note that IPCC (2001) reported almost exactly the same results.

Stern (2007) was a notable contribution to the literature spawned by the second approach because of its comprehensive coverage of available impact studies, its treatment of uncertainty and risk, its reliance on utility-based damage estimates, its expanded time horizon (the models were run through 2200), and its assumed very low discount rate. Four reported estimates of the economic effects of unmitigated climate change were expressed in terms of equivalence to a persistent average reduction in global per capita consumption; they ranged from 5% to 20% from the present into the indefinite future.

Early calculations based on the third approach – the SCC – were reported in IPCC (1996) wherein estimates ranged from $5 to $125 per ton of carbon in 1990 dollars. As reported in IPCC (2007a), Tol (2005) gathered over 100 estimates of the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.91078-X

SCC from 28 published studies. His survey showed a median estimate of $14 per ton of carbon, a mean of $93 per ton, and a 95th percentile estimate equal to $350 per ton. His survey also showed that 10% of the estimates were negative (for low climate sensitivity and underlying estimates of benefits to modest warming in some sectors). Perhaps more importantly, the 90th percentile SCC estimates were $60 per ton for studies that assumed a 3% pure rate of time preference (ppt defined as the minimum rate at which present consumption would be traded for consumption in 1 year's time) and more than $160 per ton from those who assumed a 1% ppt. The equivalent calculation for the low Stern (2007) runs produced an estimate of more than $1600 per ton.

Clearly, SCC estimates are sensitive to the pure rate of time preference; but they are also highly sensitive to other equity weighting of regional damages. Watkiss (2011) indicated, on the basis of runs of Tol's own integrated assessment model, that adding utility-based weighting would essentially double the median estimate of SCC for any ppt between 0% and 3%.

Turning now to other greenhouse gases for which there are fewer estimates, **Table 1** records mean and 5th–95th percentile ranges from Hope (2006b). It should also be noted (see Watkiss et al., 2005) that the social cost of all greenhouse gases are expected to rise over time for unmitigated futures – for example, SCC by 2–4% per year and methane by 4–8% per year (because of its shorter atmospheric lifetime).

The Economic Cost of Mitigating Climate Change

The economic cost of mitigation depends critically upon the pace and flexibility of underlying economic activity, its geographic distribution, the rate at which the future is discounted and its intertemporal distribution. Mitigation costs also depend on the design of the policy or regulatory interventions themselves; so they depend critically on the political economy of international negotiation and internal national decision-making procedures. Dynamic and spatial efficiency can reduce the cost of limiting atmospheric concentrations of greenhouse gases by 50–80%, but excessive near-term limitations of emissions can exacerbate long-term costs by comparable proportions.

Many researchers have investigated the cost of climate change mitigation. They have, in particular, focused their attention on energy consumption and the resulting emission of carbon dioxide and other greenhouse gases. Carbon dioxide, for example, is a product of burning fossil fuel, and its emission varies from fuel to fuel. Burning coal emits 25% more carbon per unit energy than burning oil, and burning oil emits 43% more carbon than natural gas. Burning hydrogen emits no carbon. Hydroelectric, wind, solar, and nuclear power are similarly carbon-free sources of energy. Mitigation therefore involves reducing energy consumption where appropriate *and* substituting carbon-free sources of energy for carbon-based fuels *and* low-carbon fossil fuels such as natural gas for high-carbon fuels such as coal. Our ability to effect and to sustain this sort of conservation and/or substitution over the very long run depends upon the availability of new technology, the supply of low-carbon and carbon-free sources of energy, as well as the political will to provide incentives, when necessary, to promote both.

Table 1 Estimates of the social cost of three greenhouse gases (in $ per ton) from a single model (PAGE 2002)

Gas	*Mean*	*5th Percentile*	*95th Percentile*
Methane	$105	$25	$250
SF6	$200 000	$45 000	$450 000
Carbon dioxide	$14	$4	$50

Source: Hope, C., 2006. The marginal impacts of CO2, CH4 and SF6 emissions. Climate Policy 6, 537–544.

The most effective means of conveying the cost of mitigation working through either route is to track estimates of the marginal cost of emission reductions. These estimates are highly model specific and they depend on the mix of energy sources assumed or determined endogenously. They all show that marginal costs increase at an increasing rate, as driven by conservation and fuel switching. **Figure 1**, included below in Section How can Mitigation Targets be Framed with such Limit Information about Damages? to illustrate a different point, clearly displays this observation for a specific example.

Article 2 of the United Nations Framework Convention on Climate Change (UNFCCC) committed the globe in 1992 to holding concentrations of greenhouse gases below levels that would imply 'dangerous anthropogenic interference with the climate system'. The precise concentration target that corresponds with this imperative has not yet been identified to everyone's satisfaction, even though two degrees has been articulated as an appropriate target (the association with a concentration target is uncertain – see NRC (2010a)). As a result, many researchers have investigated the economic cost of reducing emissions over the next 100 years so that concentrations do not exceed a range of thresholds. Manne and Richels (1997) estimated that the cost of achieving the most popular threshold among academic contributors, 550 ppmv (since lower targets now seem to be almost impossible to achieve), could be as high as $3.5 trillion (1990 dollar) or as low as $650 billion (1990 dollar). Estimates from other researchers were comparable then, and still are; but they differed from one another in specific detail for the reasons as mentioned above; again, see **Figure 1**.

Cost estimates for meeting concentration thresholds also depend critically on the location and timing of each unit of emission reduction. Wigley et al. (1996) have called this the 'where' and 'when' flexibility components of cost. Their 'WRE' results emphasize that costs would be minimized if each ton of emission reduction were taken from the least costly source regardless of where it is located; this implies that the marginal cost of the last ton of greenhouse gas emission removed from the effluent of every source should be equal. The Kyoto Protocol from the third Conference of the Parties of the UNFCCC had this goal in mind with its emission reduction targets for each country, but the inability of international negotiations to implement those plans has lead to a collection of independent bilateral agreements and regulations that do not guarantee 'where' efficiency.

The WRE results also demonstrated that emissions should be reduced at any point in time only if the discounted value of the associated cost were in line with all the discounted costs of all other reductions at all other times. These intertemporal

Figure 1 Panel A (top panel) shows trajectories for the prices of carbon (the marginal cost of emission reduction) that are consistent with achieving cumulative emission goals (increasing reductions over time against a baseline of no intervention) for six different integrated assessment models; each trajectory supports the model specific projected energy source mixes displayed in Panel B (bottom panel). Source: Figures 2.12 and 3.3 in NRC, 2010b. Limiting the Magnitude of Climate Change. National Academies Press, Washington, DC. http://www.nap.edu/catalog.php?record_id=12785, derived from Fawcett, A.A., Calvin, K.V., De La Chesnaye, F.C., Reilly, J.M., Weyant, J.P., 2009. Overview of EMF-22 U.S. transition scenarios. Energy Economics 31 (Suppl. 2), S198–S211; see www.emf.stanford.edu.

'WRE' results were controversial when they were published because 'when' flexibility implies that early reductions in emissions should be small and grow over time. The intuition behind this result is a product of the basic science of climate change. Increases in global mean temperature depend entirely on the concentrations of greenhouse gases and concentrations depend entirely on *cumulative* emissions (NRC, 2010a). As a result, determining how to achieve any concentration target at least cost is equivalent to determining how to allocate the consumption of a scarce resource (total carbon emissions over a specific or indefinite time period) optimally over time. This is the Hotelling (1931) problem for which the solution is widely known – calculate a scarcity rent and allow it to rise over time at the rate of interest so that consumption gradually falls (i.e., in this application, emission reductions climb).

Some Caveats and Open Questions

Because the analysis of climate change damages and opportunities continue to evolve and will do so for the foreseeable future, this article should be read as a brief snapshot of the state

of play as of the summer of 2013. It is fitting, therefore, to end with some coverage of issues that are on the forefront of current work.

What Is Missing from the Damage Estimates?

As noted above, current estimates of the SCC vary widely in response to the parameterization of the climate and economic systems as well as parameters that reflect normative judgments on time preference, risk aversion, and inequality aversion. This is problematic, but reasonably well understood. It must be emphasized, however, that current estimates are plagued by incomplete coverage of all of the possible effects of climate change. Figure 2 shows that many estimates of market damages for gradual climate change as well as some estimates for bounded risk and system surprises exist, and so these inform SCC calculations. A smaller number of estimates for nonmarket damages for the first two sources of risk also exist, but there is almost nothing in the literature on system surprises for this category of impact. Calculations of the SCC cannot, however, include any rigorous estimates of socially contingent damages because there are none. It follows that all SCC calculations systematically underestimate the true marginal cost of carbon, and so it also follows that the value of information derived from future research along the right-hand column and the bottom row of Figure 2 would be very high.

How Can Mitigation Targets Be Framed with such Limit Information about Damages?

Nordhaus (1991) was the first researcher to weigh the present value of the benefits of mitigation policy against the present value of their costs to compute an economically optimal policy trajectory over the long term. His results were based on the anticipation that impacts would be smooth and amount to roughly 1% of gross world product if the global mean temperature rose by 2.5 °C. Corroborated by his own subsequent work and parallel work by others, optimality calculations in the first-best deterministic analyses support modest early intervention followed by smooth and gradual tightening of emission restrictions. Indeed, most optimality exercises propose pricing carbon at between $10 and $40 per ton in 2013. All report that carbon prices should increase over time at about 3% per year (a reflection of the Hotelling result mentioned above), but none stabilize concentrations any time within the next 150 years.

As noted above, first-best calculations are suggestive, but they miss uncertainty and they miss everything that was identified in Figure 2 as an omission in the knowledge base. IPCC (2007b) includes the following language in response to this unsettling observation: "Responding to climate change involves an iterative risk management process that includes both adaptation and mitigation and takes into account climate change damages, co-benefits, sustainability, equity, and attitudes toward risk" (pg. 22). These words were unanimously agreed upon word for word by all of the countries that participate in IPCC (essentially all of the countries who have signed onto the UNFCCC).

NRC (2010b) shows how this language can be put into practice. Authors there assumed that 550 ppm was an appropriate long-term target given current information about associated economic and social risk, and they contemplated how the United States would participate over an initial 40-year time period from 2010 until 2050. The idea is that an adjustment in

Figure 2 A schematic of coverage of studies that support calculations of the social cost of carbon against source of uncertainty and socio-economic context. There are many studies in the upper left, but essentially none for combinations that would capture catastrophes (low probability – high consequence possibilities) and other extreme events (that are already being observed and, to some degree, attributed). the long-run concentration target would occur in 2050 on the basis of new science, evidence of intervening warming, evidence of economic damages distributed around the world, and evidence about the success of the global community to achieve its collective goal. In practical terms, it meant that the globe would have a cumulative emissions budget through 2050, and so the response problem in every country was to minimize the cost of holding cumulative emissions below their share of this total budget.

This allocation exercise led to the expectation that U.S. emissions should sum to something between 167 and 203 gigatons of carbon between now and 2050. Panel A of Figure 1 shows carbon-pricing trajectories that could achieve these limiting national budgets that were derived from six different integrated assessment models that included detail representations of the economics of the energy sector. Panel B shows the underlying energy mixes that each model projected over time. Diversity in what to expect in terms of energy development is clear in Panel B, but the reassuring conclusion was that any of them would be economically feasible if carbon were priced as shown in Panel A.

How or Why Should Carbon Be Priced

Pricing carbon is required not only to characterize mitigation policy, but also to internalize the value of carbon emission reductions in the evaluation of other regulations like CAFÉ standards and programs designed to promote energy efficiency – or other actions that might increase carbon emissions. Specific SCC values chosen from across the range of estimates have been used for this purpose, but they are always a bit suspect because the range is so large and they are based on incomplete knowledge.

Two other approaches have been offered. The first is supported by evidence of the type displayed in Panel A of Figure 1 – use the shadow price of carbon that is consistent with achieving mitigation targets that are derived from acceptable levels of risk. There is still no single estimate, but at least the range is smaller. The second looks at the specific technologies required to achieve those targets (from evidence of the type displayed in Panel B) and asks economists to calculate the price of carbon that would be required to make them economically feasible on a large scale. Hotelling again comes into play, because this approach suggests simply calculating a current price of carbon that would, if it were to climb at the rate of interest, reach perhaps the highest of these feasibility threshold prices at the requisite time in the future.

Abstract

A survey on climate change over the last 10 000 years is provided in this article. It highlights natural (orbital elements, solar irradiance, volcanic explosions) and anthropogenic (greenhouse) forcing. The article introduces the reader to Historical Climatology, which reconstructs weather and climate from documentary evidence on daily to seasonal resolutions. Climate change over the last millennium in China, Europe, and the Mediterranean, South America, Japan and Africa is summarized. Dealing with the societal impacts of climate requires the consideration of social and cultural factors, which underlie people's ongoing vulnerability. This article emphasizes the need for case studies combining quantitative and narrative approaches rather than demonstrating the deterministic synchrony of climate and historical events.

Introduction

Past climate has become an important issue in the climatic change debate. Though hundreds of scholars have assembled robust evidence that the world's climate has significantly changed in the past due to the anthropogenic emission of greenhouse gases, their findings are still put in doubt by a handful of scientists from outside the field of climatology (Oreskes and Conway, 2010). The first section of this article presents the main types of evidence used to reconstruct past climate and summarizes scientifically accepted results of global climate change since the end of the last Ice Age. The second section deals with the approach of Historical Climatology. The third section reviews the main trends of regional climate variability over the past millennium. Links between past climatic impacts, human perception, and social action are addressed in the last section.

Global Climatic Changes and Forcing Factors

This paragraph mainly draws on the review written by Wanner et al. (2008). For the past one million years the Earth's climate has been characterized by an alternation of glacial and interglacial episodes, marked by the waxing and waning of continental ice sheets. Over the last 9000 years the distribution of total solar irradiance was progressively reduced in the Northern Hemisphere and enhanced in the Southern Hemisphere, due to changes in the orbital parameters (**Figure 1**). After the Climatic Optimum 6000 years before the present, these tendencies led to a southward shift of the climatic zones resulting (among other effects) in the desertification of the once green Sahara.

Globally unevenly distributed, decadal to century long, warm and cold fluctuations caused by natural forcing (solar irradiance activity and tropical volcanic eruptions) and variability due to feedbacks within the climate system, were superimposed on this long-term north hemispheric cooling trend. During the Roman Period (250 BC to AD 400) temperatures in Europe were somewhat higher than at present due to orbital and solar forcing, which is an important, but often overlooked argument in the climatic change debate. The subsequent Migration Period (AD 400 to 800) was cooler. A sharp cold relapse in the AD 530s due to volcanic forcing, led to several 'years without a summer' in Europe and to drought in other parts of the world (Gunn, 2000). Climate in Europe was mild during the early millennium due to solar and orbital forcing, albeit not so warm as during the late twentieth century. Much of humanity, particularly in the Americas, Northern China, as well as in the Saharan Sahel, the Nile Valley, and Eastern Africa suffered from long periods of severe aridity (Fagan, 2008). A subsequent period of cooling, the Little Ice Age (about AD 1300 to 1900) connected to orbital forcing, reduced solar irradiance and frequent tropical volcanic eruptions and led to repeated far-reaching glacier advances around the globe. The Little Ice Age is composed of manifold monthly and seasonal temperature and precipitation patterns, also including warm phases and droughts. The global temperature rise of the last 150 years is attributed to the anthropogenic greenhouse effect, which accelerated since the 1950s in step with the increased use of fossil fuels (Pfister, 2010). "Humans are now a global force that rivals the geophysical forces of nature in many aspects" (Costanza et al., 2005: 12). Since 1990, global mean temperatures have very likely been higher than at any previous time during the last 1000 years.

The Approach of Historical Climatology

Three kinds of evidence are used for reconstructing past climate. First, proxy evidence stored in archives of nature (e.g., tree-rings and ice-cores) and second, documentary proxy evidence preserved in the archives of societies (e.g., chronicles, diaries, account books). Third, instrumental measurements of climatic elements carried out by individuals from the late seventeenth century. Such observations were institutionalized within national and global networks from the nineteenth century (Brázdil et al., 2010). Climate reconstructions in the instrumental period are reviewed in reports of the Intergovernmental Panel on Climate Change (IPCC) (Trenberth and Jones, 2007).

Climatic change is a statistical artifact that cannot be readily related to human perception and societal action. Climate sciences are directed at an improved understanding of the climate system. Starting from models of the physical world they

Figure 1 Insolation changes based on the orbital forcing during the last 10 000 years at 65° and 15° North and South during the corresponding summer season. Wanner, Heinz, Neukom, Raphael, 2010. Changes of the climate system in Europe. Nova Acta Leopoldina 112, 45–58.

extend the climate record as far back in time as possible on the basis of statistical procedures. Such macro-approaches are not suited for demonstrating people–climate interactions. Societies are sensitive and responsive to (extreme) weather anomalies taking place within daily to multi-seasonal time windows, which calls for micro-approaches. This awareness gained ground in the 1990s because an increase in weather extremes and disasters led to an additional focus on climate variability and extremes. This trend promoted a rise in historical disaster studies (Schenk and Engels, 2007) and an increasing consideration of short-term events within Historical Climatology.

The field of Historical Climatology is situated at the interface of climatology and (environmental) history, using methods and skills from both disciplines. Its objectives are threefold: First, past weather and climate of the period prior to the creation of national meteorological services are reconstructed. Second, the vulnerability of past societies to climate variations and extremes is investigated. Thirdly, debates on, and social representations, of weather and climate are explored (Pfister, 2007). Over the last 40 years Historical Climatologists (most of them being geographers, historians, and physicists) directed most of their time and effort to the collection of documentary data and the reconstruction of past climatic conditions. Given the short documentary record available to them, cooperation with archaeologists is very important for Climate Historians in North America (Carey, 2012). Until very recently climatic change was rarely addressed in syntheses of (European) environmental history, early exceptions being John F. Richards (2001) and John McNeill (2003).

The discussion on the social significance of climatic variations was long discredited by environmental determinism carried to an extreme by the geographer Ellsworth Huntington in the early twentieth century and by his followers to the present day (Fleming, 1998). The debate was relaunched from the late 1950s by the historian Emmanuel Le Roy Ladurie, a leading scholar of the French Annales School. His pioneering work was widely read and received, particularly in the English translation (Le Roy Ladurie, 1972). The English meteorologist Hubert Lamb, who took an active interest in history, became Le Roy Ladurie's most prominent opponent. He was convinced that weather and climate had affected human affairs in the past and that humankind would do well to examine some of the lessons provided by nature (Lamb, 1995).

Documentary sources contain two different kinds of evidence, namely: (1) narrative accounts on (unusual) weather spells and weather-induced disasters; and (2) biophysical evidence such as advances or delays of vegetation in the boreal summer half year and the presence or absence of frost, ice, and snow in the boreal winter half year. Another important distinction is related to the agents who kept the records, distinguishing between individuals and institutions. Individuals usually put an emphasis on describing extreme events such as floods, droughts, frosts, and hailstorms, their socio-economic impact, and their perception. They referred to biophysical evidence as a means to provide evidence that could be compared over time. Sources created by individuals are singular and relatively short, ending, at the latest, with the death of the observer. Institutions are bodies maintaining administrative functions within existing territorial structures. Their officeholders kept year by year records on weather dependent resources and activities (Pfister et al., 2009), such as the time of grape and grain harvests or the opening or closing of harbors in the Baltic (e.g., Leijonhufvud et al., 2010). Institutional functions involved more or less standardized procedures and these often worked in the same way for centuries, often generating multi-secular, long, continuous, and quasi-homogeneous series of proxy data. Ship's logbooks covering large parts of the world's oceans, including the high latitudes, are probably the most important institutional source. All officers on board of a (war) ship had to keep a logbook, which involved laying down regular observations on wind direction, wind force, weather, and – eventually – sea and ice conditions.

Logbooks usually adopt a standardized vocabulary and system of recording. Hundreds of thousands of logbooks are contained in the archives of naval powers, of which just a sample has so far been investigated in the framework of the EU Project CLIWOC (Wheeler et al., 2006).

Historical Climatologists developed a specific approach of climate reconstruction tailored to investigations on climate impacts as well as extreme value and disaster analysis. It allows integrating data on daily, monthly, and seasonal time scales into systematic monthly and seasonal reconstruction of temperatures and precipitation. Data fields containing direct narrative and calibrated indirect data are assigned synthetic ordinal (ranked) variables called temperature and precipitation indices taking a finite number of 3 to 7 values. This approach, elaborated by the Swiss historian and geographer Christian Pfister (1984) and based on preliminary work by Lamb (1977), became standard in Historical Climatology. Dobrovolný et al. (2010) used the palaeoclimatological calibration and verification approach to assess monthly and seasonal temperatures for Central Europe (Germany, Czechia, and Switzerland) from the so called Pfister Indices for the period from AD 1500 to present. The Middle Ages are included in millennium records of temperature variations for the Netherlands (Shabalova and van Engelen, 2003) as well as for Germany and Central Europe (Glaser and Riemann, 2009).

Main Trends of Climatic Variability in the Last Millennium

Today, there are six major foci of Historical-Climatologic research, namely China, Europe and the Mediterranean, South America, Japan, Africa, and the World's Oceans. For North-America, no review is available yet. In the Arab world an annalistic tradition is known to exist, but research on past weather and climate has hardly begun (Weintritt, 2009). In India, South-East Asia, and Oceania the potential for Historical Climatology still needs to be explored.

China

Ge et al. (2008) have composed a review article on climate history of China introducing the climatic information recorded in Chinese historical documents in easily understandable form and including a glossary. Systematic documentary records were kept beginning in the Qin dynasty (221 BC). The emperors strived to secure reports on current weather events and disasters from the provinces, with a view to taking timely measures to forestall the outbreak of famine-driven riots. Records mainly cover the eastern part of the country. Under the Ming Dynasty (AD 1368 to 1644) the central government called local scholars to compile the body of knowledge on past and current geography and to report on natural disasters, population, and agricultural resources. Under the Qing Dynasty (AD 1644 to 1911) administrative centers had to submit memos on their daily administrative activities to the Emperor. From AD 1736, officials were required to compile data on the duration of rainfall, including its implications for crop growth. The reports had to be prepared by the responsible officials in person and their reliability was checked. Local chroniclers recorded extraordinary phenomena in the natural world, assuming that disasters reflected on people's behavior and the government's performance. A discourse describing China as a country especially prone to natural disaster became dominant during the second half of the nineteenth century (Janku, 2009).

In South China the thirteenth century was the warmest of the last millennium. Three cold periods – AD 1470 to 1520; AD 1620 to 1740; and AD 1840 to 1890 – have been identified in the Little Ice Age. In North China two cold periods – AD 1500 to 1690 and AD 1800 to 1860 – stand out over the last six centuries. Climate variability increased markedly throughout the nineteenth century to a maximum in the early twentieth century (Wang et al., 1991).

Europe and the Mediterranean

Research in Europe was reviewed by Brázdil et al. (2010). Though some documentary evidence exists in most European countries, only a few of them have been engaged in systematic, historical-climatologic investigations: these being the Czech Republic, Estonia, Germany, Hungary, Italy, the Netherlands, Norway, Poland, Portugal, Spain, Switzerland, and the UK. Progress in climate reconstruction in these countries was spurred through EU projects. Syntheses in the form of monthly and seasonal charts, spatial charts of seasonal sea-level pressure, temperature, and precipitation dating back to AD 1500, were produced by the team led by Jürg Luterbacher (Luterbacher et al., 2002, 2004; Pauling et al., 2006).

In a diachronic perspective, the known evidence is summarized according to four cumulative time frames:

1. AD 1000 to 1200: individual reports of socio-economically significant anomalies and (weather induced) disasters.
2. AD 1200 to 1500: more or less continuous clusters of individual reports on summer and winter, partly on spring, including references to 'average' conditions. A wealth of administrative/institutional records exists in England for the period *c.* AD 1270 to 1400, which contains both direct weather references as well as institutional proxy information (Pribyl et al., 2012).
3. AD 1500 to 1800: almost complete monthly weather descriptions exist for Switzerland (Pfister, 1999), Germany (Glaser, 2008), and Czechia (Brázdil et al., 2010). The keeping of weather diaries was promoted by the rise of planetary astronomy and its application in astro-meteorology. Thirty-two sixteenth century weather diaries are so far known for Central Europe. The data obtained from these sources provided the backbone for setting up monthly precipitation statistics (Pfister et al., 1999). Institutional sources giving long series of dates of grape harvests (Daux et al., 2011) and grain harvests (Mozny et al., 2010; Wetter and Pfister, 2011) are abundant. Records of rogations (i.e., standardized religious ceremonies to put an end to meteorological stress situations) were widely used for climate reconstructions in Spain (Barriendos, 2009).
4. AD 1650 to 1860: the establishment of short-lived networks of early instrumental observations, the first being 'Rete Medicea' (AD 1653 to 1677) based in Florence and comprising 10 stations (Camuffo, 2002). A later network, the 'Societas Meteorologica Palatina,' founded 1780 by Karl

Theodor, Prince Elector of the Palatinate, included 39 individual scientists resident across Europe, in Siberia, Greenland, and North America. The Second Coalition War put an end to this organization in 1795 (Lingelbach, 1980). Regional instrumental networks were set up in the early nineteenth century, which were integrated into national and global networks after 1850.

Subsequent climatic trends are summarized: after a cold phase in the twelfth century, winters were prevailingly warm from AD 1180 to 1300. From AD 1300 to 1900, the winter half-year was colder than today, due to more frequent advection of cold, dry air-masses from the Northeast. Springs were extremely cold in the 1690s and the 1740s. Summers in the thirteenth century were prevailingly warm and dry. In the fourteenth century, clusters of cold and wet summers occurred repeatedly (e.g., in the 1310s and 1340s). April to July temperatures in England dropped by 0.6 °C from AD 1256 to 1431, affecting the economy by a higher frequency of extremely cold 'growing seasons' (Pribyl et al., 2012). From AD 1380 to 1430 and again from AD 1530 to 1565 the summer half-year was as warm as it is today.

Cold spells and long rains in midsummer became more frequent in the late sixteenth century (Pfister, 2007). The period AD 1640 to 1650 witnessed harsh weather and severe famines in many countries, also outside Europe (Parker, 2008). Warm decades stand out in the 1720s, the 1730s, and in the 1780s in Western and Central Europe, whereas the first half of the nineteenth century, particularly the 1810s, were markedly cooler (Bradley and Jones, 1996; Pfister, 1999; Glaser, 2008).

Winters in Russia became more severe from the end of the sixteenth century, in particular from AD 1620 to 1680 and during the first half of the nineteenth century. The first half of the sixteenth century was warm in all seasons. Subsequently, cold spells occurred more often from AD 1590 to 1620 and from AD 1690 to 1740, with a peak in the 1730s. Droughts were frequent from AD 1201 to 1230, AD 1351 to 1380, and AD 1411 to 1440; and again from AD 1640 to 1659, from AD 1680 to 1699, and from AD 1801 to 1860. Summers from AD 1890 to 1920 were the coldest in the last 500 years and extremely dry and wet seasons were frequent (Bradley and Jones, 1996).

Climatic trends in the Mediterranean since AD 1500 were reviewed by Luterbacher et al. (2006). Winter temperatures were, with respect to AD 1961 to 1990 averages, almost consistently colder until the 1950s. In Catalonia (Northeastern Spain) dry spells in the winter half-year were frequent in the mid sixteenth century, but almost absent from AD 1580 to 1620 (Barriendos, 2009). The Mediterranean witnessed increased precipitation in the form of torrential rain and, at times, increased snowfall at higher altitudes (Tabak, 2008).

South America

The Argentinean historian and geographer Maria Rosario Prieto reviewed the studies in this continent up to AD 1810. Most work was done in Ecuador, Bolivia, Peru, Chile, and Argentina, although evidence also exists in other countries. The Spanish colonization of America from the sixteenth century relied on a rampant bureaucracy. The resulting documentation includes weekly reports on notable incidents including weather, harvest expenditures, and food supplies. Sources from priests, military officers, or civilians, such as letter collections, travel journals, annals, or diaries provide more continuous information. From AD 1784 the Spanish Crown asked each municipality to submit a half-yearly report about weather (impacts), agriculture, and trade. Logbooks of ships sailing the surrounding oceans provided daily information on winds and weather conditions. The transition to the Republican period after AD 1810 led to gaps in the record. Newspapers became a useful source of information in the postcolonial period. The first meteorological stations were established in the late nineteenth century.

In most regions, cold conditions prevailed from the late sixteenth to the early seventeenth century (e.g., in Central Europe). The Mendoza river streamflow in Argentina was smaller from AD 1600 to 1670, due to lower summer temperatures and reduced melting of snow in the Andes. A long, cold interval from AD 1520 to 1660 stands out in the Northern Patagonian Andes (Rosario Prieto and García-Herrera, 2008).

Japan

Historical Climatology in Japan was reviewed by the geographer Takehiko Mikami. Climatic trends in the 'pre-instrumental' period are based upon three kinds of proxy-data. (1) The annual dates when Lake Suwa in central Japan froze have been recorded since the fifteenth century, and these dates are highly correlated to December and January temperatures. When Lake Suwa freezes, the shrinkage and expansion of the ice due to diurnal temperature variations produces a specific feature (Omiwatari) resembling a bridge over the lake. The annual appearance of Omiwatari gave rise to a celebration the date of which was recorded and retained. (2) Cherry blossom is known in Japanese culture as a symbol for the ephemeral nature of life. Picnicking under a blossoming cherry tree (hanami) became first a custom of the Imperial elite in Kyoto and spread then gradually to other strata of society (http://en.wikipedia.org/wiki/Cherry_blossom). Year-to-year variations in full flowering dates of cherry trees in Kyoto were recorded since AD 1001 and were used as a proxy for estimating March temperatures. (3) Families in many parts of the country kept weather diaries from the early eighteenth century. Based on this evidence, July temperatures in Tokyo from 1721 to the present, have been estimated.

Reconstructed mean December–January temperatures were 1 to 1.5 °C lower in the early 1600s than in the years AD 1961 to 1990. Winters then warmed up between AD 1750 and 1850. March temperatures were higher during the eleventh to the thirteenth centuries and relatively lower during the Little Ice Age. Estimated July temperatures from AD 1721 to 1790 were 1 to 1.5 °C lower than in the years AD 1961 to 1990. Midsummers were rather warm in the nineteenth century. A cold relapse down to the low level of AD 1740 occurred around 1900 (Mikami, 2008).

Africa

The evidence for the last two centuries was reviewed by the climatologist Sharon E. Nicholson. Few instrumental records

exist prior to the twentieth century, and most of these dealt with rainfall. However, documentary proxy information permits a quasi-continuous record on precipitation patterns since the early eighteenth century. Nineteenth century rainfall variability in Lesotho (Southern Africa) was investigated by Nash and Grab (2010).

During the Medieval Warm Period and again from the sixteenth through the eighteenth centuries, Northern and Southern Africa benefited from rather humid conditions. From the late eighteenth century arid conditions prevailed again, particularly during the 1820s and 1830s. Since then, several periods of abundant rainfall (AD 1860 to 1894; in the 1920s and 1930s; in the 1950s) alternated with periods of severe drought (in the 1910s and the 1960s) to the present. Nicholson argued that the recent droughts in Africa are more driven by changing rainfall than by land-use change and desertification (Nicholson, 2001).

Weather, Climate and History

Human history is usually cast in terms of the rise and fall of great civilizations, wars, and specific human achievements, leaving out the ecological and climate context, which shaped and mediated these events (Costanza et al., 2005). However, "the inclusion of the climate factor in the study of history should not be regarded as a search for an alternative, and deterministic, explanation of the past, but as an expansion of the context in which the workings of past societies are to be understood." (De Vries, 1985: 274). Indeed, the effects of climatic fluctuations or 'climate' on the course of 'history' are difficult to demonstrate, because both climate and history are blanket terms, situated on such a high level of abstraction that relationships between them cannot be investigated in a scientifically meaningful way. On a very general level, it could be said that beneficial climatic effects tend to enlarge the scope of human action, whereas climatic shocks tend to restrict it. The sequences of climatic situations that mattered, depended upon the vulnerability of the impacted groups and societies to climatic hazards (Pfister, 2007). Social (or internal) vulnerability encompasses the entirety of structural factors that determine the outcome of an event of a given nature, as well as the severity of factors such as poverty, dependence on outside support, and the ability to cope with specific hazards (Füssel, 2007). Striking differences of vulnerability may arise within very small areas, as the example of Switzerland in the European subsistence crisis of 1816/17 demonstrates. Whereas the easternmost proto-industrialized parts of the country, cut off by embargoes from their main breadbasket in neighboring Germany, suffered from famine, the western region being almost self-sufficient, only underwent a mild form of food deprivation (Krämer, 2012).

In many cases, however, investigations of climate and history limit themselves to hinting at the synchronicity of climatic and economic events. A recent example is a tree ring-based study linking the temperature depression of the early seventeenth century in Europe with the Thirty Years War (Büntgen et al., 2011). With regard to China, Zhang et al. (2007) correlated analyses of natural proxy data from national archives with hypothesized data on harvests and demography, to demonstrate interrelations between climatic change, the frequency of conflicts, and dynastic rise and fall. A study on the relationship between frequency of wars and climate in Europe was attempted by Tol and Wagner (2010). Historian Ka-wai Fan (2010) argues that scientists too often fail to acknowledge the complexity of history and the overwhelming role played by human beings. Indeed, the authors of all three above mentioned papers overlooked the truism recalled by Martin Parry (1981) that "an investigation of the synchronicity of climatic and economic events infers a space–time coincidence rather than causality." (p. 321). Nico Stehr and Hans von Storch (2000) note in this context that "a large proportion of today's climate impact research is genuine climate determinism" (p. 187).

A human history of climate should highlight those extreme climate anomalies that are known to have affected everyday life and disrupted daily routines. In particular this relates to those conditions on which humans depend for their basic needs and well-being, i.e., the availability of water, food, and energy. Every vulnerability analysis needs an appropriate focus, considering of course, the interrelationships of the many dimensions of vulnerability (see **Figure 2**).

Food availability is a major focus of (historical) climate impact studies. A history linking climate and society should draw on extreme events and highlight changes in the frequency of weather spells that were recognized by contemporaries to be responsible for widespread weather-related crop failures. In any case, the contexts of historical events need to be highlighted to provide meaningful explanations.

There is agreement that societies do not just react to climatic stimuli. Brian Fagan (2008) was amazed "how remarkably flexible human societies were in much of the world one thousand years ago" (p. 236). Climatic impacts become critical, "when a society reached a critical mass, a density of urban population and nonfarmers that was unsustainable in drought cycles or an agrarian economy that had exhausted the land and all opportunities for diversification" (p. 237). As Jared Diamond (2005) put it: "One of the main lessons to be learned from the collapse of past societies […] is that a steep decline may begin only a decade or two after a society reached its peak numbers, wealth and power" (p. 509). The reaction of the ruling elites to climate and environmental change may be decisive for the survival of states and empires in such situations. Besides the well-known paradigm of Easter Island (e.g., Diamond, 2005), the example of the Western Roman Empire, (a large, multicultural state entity of the size of the European Union) is worth recalling in this context: The cooling trend from the late second century AD affected the size of harvests and thus the revenues of the Empire. The imperial bureaucracies and the army were so much expanded, that the taxable peasants became unable to bear the tax burden in the context of falling harvests; and they fled the land leaving large arable tracts uncultivated. In the end, the Emperor could not pay his armies any more, whereupon these seized power and deposed him (Tainter and Crumley, 2005).

In a seminal article Robert W. Kates (1985) distinguished several levels of climatic impacts (see **Figure 3**). Their sequence and the size of the intermediate arrows indicate, how closely these effects are related to climatic impact.

Figure 2 Impacts of extreme climate events on societies. Pfister, Christian, 2007. Climatic extremes, recurrent crises and witch hunts: strategies of European societies in coping with exogenous shocks in the late sixteenth and early seventeenth centuries. The Medieval History Journal 10, 1–41.

Figure 3 A basic model of climatic impacts on society. Kates, Robert W., 1985. The interaction of climate and society. In: Kates, Robert W., Ausubel, Jesse H., Berberian, Mimi (Eds.), Climate Impact Assessment: Studies of the Interaction of Climate and Society, vol. 27. John Wiley & Sons, Chichester, 3–36; Pfister, Christian, 2007. Climatic extremes, recurrent crises and witch hunts: strategies of European societies in coping with exogenous shocks in the late sixteenth and early seventeenth centuries. The Medieval History Journal 10, 1–41.

The quantity and storability of crops situated on the first level are most immediately related to the weather. However, most members of premodern societies had developed sophisticated strategies (e.g., horizontal and vertical crop diversification) to cope with the risk of harvest failure. Fluctuations in food prices are among the most obvious second-order consequences. Climatic effects on this level are, however, masked by intervening factors, such as trade, the stocking of

public grain, hoarding, and speculation. Third-order effects, such as demographic effects, are intertwined with epidemiological and public health contexts in ways that are highly controversial. Malnutrition is known to be contingent on distributional systems, in turn dependent on power relations, factors of class and gender, and the supportive capacity of social networks. Whether famines resulted in social upheaval largely depended on the quality of governance. The farther we move away from first-order effects, the broader are the options open to individual or collective actors. Likewise, the web of factors masking the climatic effect gets to be more complex. Of course, the one-directional, top-down arrays are heuristically motivated oversimplifications. As is well known, the role of feedback is crucial in complex socio-ecological systems, and a it is major reason why simple cause and effect paradigms often have little explanatory power (Costanza et al., 2005: 14).

A major difference in dealing with climate impact studies relates to the fact that natural sciences mainly depend on quantitative or quantified data, while human sciences mainly draw on narrative or qualitative evidence. Case studies in terms of absorbing narratives are closest to people's perceptions and experiences, but they are hardly suited for generalizations. In some cases it may be possible to model relationships between weather, harvests, and prices (e.g., Pfister and Brázdil, 2006). In general, cold periods in March and April and rainy midsummers affected the quantity and quality of all sources of agricultural produce in temperate Europe (Pfister, 2007). Cultural analyses of climate change illuminate the response of 'real people' to climate change. At present, it is scientifically accepted "that climate is both the physical characteristics of the climate system and a cultural construction that emerges from perceptions, meanings, spirituality, discourse, and distinct knowledge bases that vary in time and space" (Carey, 2012; Daniels and Endfield, 2009).

Abstract

Although psychology as a discipline is held to have originated in Europe with Wundt's laboratory in Leipzig in 1879, clinical psychology emerged in Europe substantially after the World War II in the 1940 and 1950s when Europe was rebuilding itself and its health and welfare systems. Europe is characterized by the diversity of its 48 or so countries which have different histories and social, intellectual, and cultural traditions which have affected the development of the profession and practice of clinical psychology. Nevertheless, since the 1950s with the increasing professionalization of clinical psychology, leading to increased length of education and training, the development of ethics codes, growing regulation, and legislation in relation to the profession, and in 1981 the formation of the federation EFPPA (European Federation of Professional Psychologists Associations), there has been a gradual move toward more common standards and an attempt to develop a European framework for different areas of training and practice. This trend is likely to develop well into the mid-twenty-first century with a greater unification of Europe.

Introduction

Europe is characterized by its social, linguistic, and cultural diversity (e.g., Drenth et al., 1990; Poortinga, 1996), which is rooted in very different histories and traditions of the 48 or so countries. Even the geographical or political extent of Europe is a matter for some debate, though it is assumed that the growth of the European Union (currently 15 states, all of them in western Europe) will clarify this in future years. Although psychology as a discipline originated with Wundt's laboratory in Leipzig, Germany, in 1879, the profession of clinical psychology was considerably slower to develop in Europe than in the USA (Sexton and Misiak, 1976; Eysenck, 1990; Sexton and Hogan, 1992).

The major influence for the development of clinical psychology in many western European countries was the rebuilding of Europe after World War II in the 1940s and 1950s and the development of mental health facilities by European states, as the challenge of mental problems and mental health presented itself to health authorities (Lunt, 2000). In eastern European countries clinical psychology developed much later as these countries emerged in the 1980s from political regimes which were critical of the discipline (e.g., Pawlik, 1996). It is only relatively recently that these countries have begun to develop a profession of clinical psychology.

The Field of Clinical Psychology

Although there are differences between countries, it is possible to provide a general definition of the field which would be agreeable to all European countries; clinical psychologists may be defined as psychologists who

> apply psychology in a clinical context, usually a hospital, medical or community setting, with people (patients or staff) who consider themselves to be in need of a psychological perspective on their lives. In practice, the majority of clinical psychologists contribute to the assessment and treatment of people who see themselves as having psychological problems, such as those with mental health difficulties, but they also work with the handicapped, families, those with learning difficulties, and, more widely, with staff and organisations.
>
> Llewelyn, 1994

There are some differences in the practice of clinical psychology, from countries where the majority are employed by the state such as the United Kingdom where most clinical psychologists work for the National Health Service (NHS) and there is relatively little private practice, to countries such as Switzerland and Germany where many clinical psychologists work in private practice, with charges reimbursed by medical insurance companies. Furthermore, there are differences in the dominant activity of clinical psychologists: in many European countries the main activity is psychotherapy, whereas in others there is a broader role which includes assessment and other forms of intervention, and also a role in training and consulting with other staff. While the dominant paradigm informing clinical psychology in the United Kingdom is cognitive behavior therapy, other European countries such as France and Italy historically have been more influenced by psychoanalytic ideas. Although all European countries have been influenced by the USA, this influence has been perhaps most striking in the Scandinavian countries which embraced the 'scientist practitioner' approach to practice from an early stage.

Europe

As mentioned, the political face of Europe is developing and changing rapidly (see Lunt, 1998). Many of the central and eastern European countries have applied for membership of the European Union, and are working toward criteria which will enable them to join. This will mean an expanded and changed Europe in the not too distant future, bringing together the early members of the European Union and nonmember states; many of the latter in Eastern Europe and formerly belonging to the Soviet Union. The countries of Europe

constitute a very diverse group that may nevertheless be grouped into broad regions with some commonality in their organization and practice of clinical psychology. For these purposes, at a very broad level it is possible to identify a Nordic group of countries with considerable commonalities in their practice (the Scandinavian countries), Great Britain which has much in common with education and training in the USA and other parts of the English-speaking world, the German speaking countries, a southern European group, and an eastern European group. Of course, within these regions, the countries are characterized by their individuality and their diversity, and the different histories that have had a profound influence on the development of clinical psychology.

The Early Years of Clinical Psychology

There are a number of models in the field of clinical psychology, a field which emerged in European countries substantially after World War II (see above). It emerged as a recognizable profession at different times in different countries. In the United Kingdom the two World Wars provided a significant impetus to the emergence of this profession, initially through the need to develop psychological tests to recruit suitable personnel, and later in 1948 with the formation of the NHS that provided a considerable impetus to the development of this new profession. In these early days, the role of the clinical psychologist was largely one of laboratory technicians administering psychometric and other tests, usually for medical practitioners (Eysenck, 1990). However, in the United Kingdom, the development of behavior therapy, in particular under the influence of Hans Eysenck who established clinical psychology as a profession in England in 1949, led to clinical psychologists developing a therapeutic role, and by the 1960s they had become clinical practitioners in their own right.

In the Nordic countries, also, clinical psychology emerged substantially after World War II, in the 1940s and early 1950s; the Norwegian Psychological Association was founded in 1934, the Danish Psychological Association in 1947, the Swedish Psychological Association in 1955, and the Finnish Union of Psychologists in 1957. The formation of these Psychological Associations reflected the emergence in these countries of a profession of psychology, mainly clinical psychology, which progressed through similar broad major phases as the UK; that is, a phase focusing on diagnostic examination and testing of individual patients, a phase focusing on therapeutic work involving mainly psychotherapy, and a phase focusing on indirect work with other professional groups through techniques such as consultation and training.

In Spain, on the other hand, clinical psychology has had a shorter history (Belloch and Olabarria, 1994) and is said to have emerged in the 1970s along with fundamental changes in Spanish society. Similarly in Italy, clinical psychology as a professional application emerged substantially in the 1960s and there remain some tensions over the autonomy and role of clinical psychologists and their relationship with medical practitioners, especially psychiatrists. The Association of Greek Psychologists, founded in 1963, reflects the existence of professional psychology in Greece, although at that time and until very recently, all clinical psychologists received their training overseas, and the profession was very much dominated by the medical profession.

As mentioned above, clinical psychology emerged much later in Eastern European countries, and it was not until the 1980s that psychotherapy was fully recognized as a profession (Pawlik, 1996). Until recently, nearly all psychologists were employed in state institutions, though in recent years there has been a growth in demand which has resulted in a growth in private practice.

In all European countries, clinical psychologists represent the largest group of psychologists, and experienced a rapid growth in their number between the 1960s and the 1990s with the expansion of mental health provision and the growing awareness of the contribution of clinical psychology to a wide and diverse range of areas of work (EFPPA, 1997). Indeed, the 31 Member Associations of EFPPA (see below) represent 150 000 psychologists, the majority of whom are clinical psychologists.

Since the 1990s, in many European countries the emergence of the specialty of health psychology, with a focus on prevention rather than treatment, and the promotion of health rather than a more therapeutic or curative function, has led to attempts to define and differentiate a new field of psychological activity within the mental health field. This has been supported by the WHO commitment to Health for All by the Year 2000; EFPPA has had three Task Forces, focusing respectively on clinical psychology, health psychology, and psychotherapy, which have drawn up a model defining overlap and separate areas of activity within the health field, with corresponding commonalities and differences in education and training (EFPPA, 1997).

Training of Clinical Psychologists

Education and training of clinical psychologists varies in European countries though, again, there are major regional groupings. Across Europe, as in other regions of the world, the education and training period has increased, with moves in some European countries for doctorate training for clinical psychologists, and more demanding requirements in all countries for the internship period. In the United Kingdom, there is a strong commitment to a scientist-practitioner model: 'the clinical psychologist is first and foremost an 'applied scientist' or 'scientist-practitioner' who seeks to use scientific knowledge to a beneficial end' (Marzillier and Hall, 1990). This commitment also characterizes the Nordic countries which have been influenced substantially by the USA, and also by the UK. These countries would sign up to the definition that:

> clinical psychologists share several common attributes. They are psychologists because they have been trained to use the guidelines of knowledge of psychology in their professional work. They are clinicians because they attempt to understand people in their natural complexity and in their continuous adaptive transformations … they are scientists because they utilize the scientific methods to achieve objectivity and precision in their professional work. Finally, they are professionals because they render important human services by helping individuals, social groups, and communities to solve psychological problems and improve the quality of life.
>
> Kendall and Norton-Ford, 1982: p. 4

This model is also espoused by Spanish clinical psychology where Belloch and Olabarria (1994) state that clinical psychology training is 'very similar to that proposed in the 1940s, in the famous Boulder Conference, organised by the APA.' In France, where there is a strong clinical psychoanalytic tradition, there is less of a commitment to the 'Boulder' model, and more of a philosophical or hermeneutic tradition in relation to education and practice.

However, since 1957 when the Treaty of Rome provided the foundation for the European Community (later Union), there have been requirements on individual countries ('states') to provide procedures for the mutual recognition of psychologists' qualifications across national boundaries (see McPherson, 1988). Wider moves within the European Union such as the Bologna Agreement, which was signed by 29 Ministers in 1999 and commits them to greater convergence in terms of university degree structures, mean that even within Europe there is likely to be greater similarity in terms of structures of education and training for clinical psychologists.

Professionalization of Clinical Psychology

The period since the 1950s has seen a greater professionalization of clinical psychology in all European countries, with the development of codes of ethics (Lindsay, 1996) and increased regulation and laws for clinical psychologists (Lunt, 2000) across European countries. These political and professional developments have been supported by EFPPA which has brought together clinical psychologists from all over Europe to work on the professional aspects of practice at a European level and to support individual European countries seeking to develop their ethical codes, laws protecting the title of psychologist, and education and training in clinical psychology.

Organization of Clinical Psychology

It is also possible to trace the history of clinical psychology through its organization in Europe (Gilgen and Gilgen, 1987; Lunt, 1998). Many European countries founded scientific societies for psychologists in the early twentieth century whose purpose was to foster research and psychological science. At the time of World War II, separate professional associations to meet the needs of professional psychologists, often mainly clinical psychologists, were founded in a number of European countries. These associations had, as a focus, issues concerning professional practice and emerged in some countries as Trade Unions, negotiating salaries and terms and conditions of work for clinical psychologists as well as wider professional issues such as regulation, legislation, and ethical codes. In 1981, at a time when the provisions of the European Community demanded that European member states encourage mobility of professionals across Europe, the European Federation of Professional Psychologists Associations was formed to bring together professional associations in Europe and to collaborate on matters of common professional concern.

EFPPA currently has 31 member associations representing all the countries of the EU, all other countries in western Europe, and a growing number of member associations from central and eastern Europe. The federation provides a unique opportunity for comparison between the practices of different European countries and a forum for discussion and debate of important issues. The formation of EFPPA in 1981, when matters of mobility and mutual recognition were becoming more pressing, was due to a realization by psychologists and psychology associations of member states that a federation would provide a professionally and politically useful way to move forward and to begin to develop common policies in this area. Clinical psychologists, in particular, were faced with the growing prospects of mobility between countries in the European Union, and the implications of the Treaty of Rome that provided the foundation for the European Community in 1957.

As a federation of Professional Psychology Associations representing around 150 000 professional psychologists in Europe, EFPPA spends most of its efforts on clinical psychology and clinical psychologists, also the largest group of psychologists within Europe (as in the rest of the world). In many countries psychology has become one of, if not the, most popular subjects to study at university. The majority of students studying psychology aspire to become clinical psychologists, and for this reason, in many European countries, there is an oversupply of qualified practitioners. Many countries now operate a so-called *numerus clausus*, either at the start of the psychology study, or during the study. This controls the numbers in training. In the United Kingdom, where specialist training in clinical psychology is funded by the NHS – where the vast majority of clinical psychologists work – the number of 'trainee' posts is strictly limited and is planned according to staffing needs in the different regions of the country. In other countries, where there is a tradition of predominantly private practice in clinical psychology, there are large numbers of qualified psychologists unable to find work. In all European countries, the ratio of female to male students is between 6:1 and 3:1, leaving the profession in danger of becoming an almost feminized profession in the future (Schorr and Saari, 1995). There has also been some difficulty in many countries in recruiting students from the range of ethnic groups represented in Europe's increasingly multiethnic population. This clearly has implications for the clinical treatment of different client groups.

The Future

As new fields of practice in the health field evolve, in particular health psychology, there are pressures on clinical psychology. For example, in some countries it has been said that there may no longer be a field of clinical psychology, since there are strong moves toward a broader field of health psychology and a greater focus on preventive work. These newer areas, such as health psychology, neuropsychology, and forensic psychology, are leading to greater specialization within and outside clinical psychology. Although European countries differ in the extent and nature of their specialisms within the health field, there is an increasing trend for specialization and demands for higher qualifications. In one respect, psychologists working within the health system could be said to be becoming more generic,

while on the other hand there are increasing specializations within this field of work.

Summary

The brief 50-year history of clinical psychology in Europe has seen an enormous increase in numbers both of students and of practitioners, such that the majority of psychologists are now clinical psychologists. This rapid professionalization has been accompanied by higher qualifications, greater regulation, the development of ethical codes, and all the characteristics of traditional professions. However, as the number of clinical psychologists increases, and the question of mobility across Europe becomes more pressing, there will be increasing attempts to develop more common frameworks and standards for education and practice; the challenge will be to achieve a balance between allowing individual countries their own autonomy which reflects their differing history and culture ('subsidiarity' as it is called), and developing more common agreed frameworks of practice which reflect a possible future 'federalization' of Europe.

Abstract

The first psychology clinic in the world was founded by Lightner Witmer at the University of Pennsylvania in 1896. Clinical psychologists in the United States first organized themselves in 1917. This field was greatly expanded after World War II with funds from the US government for training. In Canada and Mexico, clinical psychology developed mostly after World War II. Thus, a 1965 conference in Canada endorsed the doctoral training model previously developed at a 1949 conference in the US. In French-speaking Canada, masters level training was more typical, whereas in Mexico a 6-year 'licentiate' degree prevailed. Today, in North America as elsewhere in the world, clinical psychology is concerned with the study of psychopathology and with its diagnosis and treatment.

Clinical psychology is concerned primarily with the study of psychopathology and with its diagnosis and treatment. It shares this domain with several other mental health disciplines, including psychiatry, social work, nursing, and various types of counseling. Compared to these other disciplines, clinical psychology is distinctive for its training in research and for its expertise in psychometrics and the behavior therapies. North America played an important role in the emergence of clinical psychology. The field usually dates its origin from the founding of the first psychology clinic in 1896 by Lightner Witmer (1867–1956) at the University of Pennsylvania (Routh, 1996). Clinical psychology in the English-speaking parts of Canada developed in a pattern similar to that seen in the US (with doctoral training required for independent practice) but somewhat later in time. The field developed in French-speaking Canada and in Mexico in a way more resembling that of European countries, with master's or licenciate-level training required for independent practice. The North American Free Trade Agreement now exerts pressure on all three countries and their states and provinces to coordinate these differences to a greater degree, to permit more freedom of movement to qualified clinical psychologists.

The Prehistory of the Mental Health Field

The need for humans to deal with the problems now called mental illness did not emerge suddenly a century ago. It seems reasonable to assume that such problems have existed in some form in every society through all the millenia of human experience. The ancient literature of India, Egypt, China, Greece, and Rome contain descriptions of disturbed behavior, often interpreted in religious terms as some type of retribution by magical or divine forces. Legal systems as they developed in all of these civilizations necessarily included provisions for seeing to the management of the affairs and property of persons who were temporarily or permanently unable to manage for themselves (Routh, 1998).

Greek Ideas Concerning Psychopathology

Western concepts of psychopathology have their roots in those of the ancient Greeks, including the writings attributed to the physician Hippocrates (460–377 BC). These Hippocratic writings include terms such as melancholia, mania, paranoia, and dementia, with meanings not all that different from their present ones, albeit with different explanations. For example, in Greek, the word 'melancholia' simply means 'black bile.' In the Hippocratic theory of the humors, a person suffering from severe mental depression had an overabundance of black bile, a substance thought to be produced by the spleen. Within this system, one aspect of treatment quite reasonably aimed to reduce the amount of black bile by administering a purgative such as hellebore. Another disorder was that of 'phrenitis,' literally meaning an inflammation of the mind. This referred to mental disturbance accompanied by fever, and the approach taken was simply to wait for the fever to abate. Though some of these Hippocratic ideas may seem strange to us now, it is worth reflecting why some of them lasted well into the eighteenth century and beyond.

Emergence of Psychiatry

Although according to Herodotus (*c*.484–425 BC), medical specialties existed even in ancient Greece, the one we now call psychiatry did not emerge until the late eighteenth century in Europe. The ancients did not conceptualize mental disorders as a separate category but regarded them as being illnesses like any other. When psychiatry did emerge, with the work of such pioneers as Philippe Pinel (1745–1826), Benjamin Rush (1745–1823), and Vincenzo Chiarugi (1759–1820), it was associated with the development of mental asylums or hospitals as a separate locations for the care of those with mental derangements. The theory of 'moral treatment' that was typical of that time tried to minimize the use of coercive methods such as chaining patients to restrain them and instead insisted that they be treated with kindness and courtesy. It was often found that even some very disturbed patients responded positively to such a regimen.

Modern Psychology and the Study of Psychopathology

Long before a formal discipline of psychology existed, people in every society still no doubt reflected upon human experience

and behavior. As was the case of Hippocrates in relation to medicine and psychiatry, the influence of ancient Greek philosophers such as Plato (427–347 BC) and Aristotle (384–322 BC) upon our present psychological concepts was pervasive. There is conventional agreement that psychology emerged as a formal academic discipline only in the mid-nineteenth century in Europe. Wilhelm Wundt (1832–1920) of the University of Leipzig is usually named as the founder of the field, and 1879, the year in which he set up his psychology laboratory there, is celebrated as the key event in its origin. Wundt's work and those of the other early psychologists often focused on sensory processes, reaction time, and memory. It is also noteworthy that the study of psychopathology was a possible topic of psychological study even in those days. The eminent psychiatrist Emil Kraepelin (1856–1926) was influenced by Wundt's writings and was interested in psychology. His main motive for becoming a psychiatrist was that this was the only way he could see to make a living while doing psychological research. He later actually studied under Wundt, who encouraged him to keep on with his work combining psychology and psychiatry. Kraepelin set up psychology laboratories at his psychiatric clinics in both Heidelberg and Munich.

Many of the pioneers in psychology in both Europe and the US were trained as medical doctors. In France these included Theodule Ribot (1839–1916), who wrote about diseases of memory and about personality disorders. An important French colleague was Pierre Janet (1859–1947), who studied anxiety, hysteria, and obsessions and developed concepts of dissociation that continue to be influential today. In the US the leading pioneer in psychology, William James (1842–1910) was originally trained in medicine but wrote a psychology textbook that proved to be the most influential of all. In 1896, James gave his Lowell lectures on exceptional mental states, much influenced by the work of Janet. Boston neurologist Morton Prince also became interested in Janet's writings and published a description of a woman with multiple personalities who had been his patient. Prince established the *Journal of Abnormal Psychology* in 1906 and later gave it to the American Psychological Association. Subsequently, in 1926, he established the Harvard Psychological Clinic, which was a research facility rather than one delivering mental health services. The most influential medically trained student of psychology of this time was no doubt Sigmund Freud (1856–1939). Breuer and Freud's book *Studies in Hysteria*, was published in 1895 and Freud's book on the interpretation of dreams in 1900. The first international psychoanalytic meeting was held in Salzburg in 1908. In 1909, Freud came to the US for the first and only time.

Lightner Witmer and Clinical Psychology

As the above paragraphs make clear, Witmer was hardly the first to suggest that psychologists study psychopathology. Instead, his main contribution was to go beyond that to advocate that psychologists try to help people as well as study them. Witmer had been an undergraduate at the University of Pennsylvania and then for a time, before going to Leipzig to obtain his PhD under Wundt, served as a school teacher. He had as a student a young man with marked difficulty in reading and was able to help the youngster succeed in school and go on to attend college. This turned out to be a formative experience for Witmer. After Witmer had obtained his PhD and returned to his *alma mater* as a psychology professor, a school teacher named Margaret Maguire asked his advice about one of her pupils with a spelling problem. Witmer reasoned that if psychology was of any practical use, it should be able to be of help in a case of this kind. Thus was the psychological clinic and the field of clinical psychology launched.

Witmer's clinic worked more with children than with adults and tended to concentrate on academic difficulties such as reading, spelling, or general backwardness in school as opposed to emotional or behavioral problems. His historic forebears are thus not Hippocrates and Pinel but rather eighteenth and nineteenth century French physicians and special educators such as Jacob Pereire (1715–80) (who taught deaf-mutes to speak), J.M.G. Itard (1775–1838) (who worked with the 'wild boy' of Aveyron), and Edouard Seguin (1812–80) (a physician who devised a 'physiological method' of sensory and motor training in an attempt to remediate mental retardation). Witmer used existing laboratory procedures including the Seguin formboard and sensory/motor procedures adapted from Wundt to evaluate the children referred to him and often tried to teach them simple tasks as a part of his diagnostic efforts. In his treatment activities he often collaborated with school teachers, as well as with physicians, thus serving as more of a consultant than doing anything resembling present-day psychotherapy. As a matter of fact, he was little influenced by the activities of the Boston School of psychotherapy that was contemporary with his work, nor later by Freud and his psychoanalytic movement.

Witmer is not remembered for any noteworthy scientific discoveries but rather for his persistence in enacting this new role of the clinical psychologist. At the University of Pennsylvania's PhD program, he essentially trained most of the first generation of clinical psychologists. He maintained his clinic as a service and training facility and in 1907 began a journal, the *Psychological Clinic*, to publicize these activities (Witmer, 1907).

The Binet Test

There is still no consensus among psychologists as to precisely how to interpret its findings. Still, Alfred Binet's 'metric scale' of intelligence (Binet and Simon, 1905) may be the most noteworthy piece of technology developed by psychology in its first century. Certainly it had a major impact on the new field of clinical psychology. In fact, before World War II, probably the most characteristic activity of the typical clinical psychologist was the administration of the Binet test and other similar measures (Routh, 1994). This was true despite the fact that Lightner Witmer, the founder of the field, was quite critical of the Binet test and used it only as one part of his extensive battery of laboratory procedures.

In the light of how influential his test was, it is interesting to note that Alfred Binet himself was not particularly identified with the field of clinical psychology. Originally trained as a lawyer, Binet became part of the circle around the influential neurologist Jean Charcot at the Salpetriere in Paris. Much of his psychology was self-taught, through extensive reading at the

Bibliothéque Nationale. In France, Binet became known as one of the founders of the entire field of psychology (often characterized worldwide as 'experimental psychology') and edited the influential journal, *Annee psychologique*. As is well-known, Binet's successful attempts to devise an intelligence test departed from the conventional approach of using relatively 'pure' sensory and motor tasks to use complex worksamples of the kinds of things school children might be expected to know and do.

For some reason, Binet's new test did not create as much of a stir in his homeland as it did in the US. Psychologist Henry Goddard, who directed the psychology laboratory at the Vineland Training School, in New Jersey, had the Binet test translated and soon confirmed its impressive validity in identifying persons with mental retardation. The use of the Binet spread like wildfire among the early clinical psychologists in the US, beginning with those employed in the field of mental retardation. Goddard founded the first psychology internship in 1908 at Vineland, NJ. Goddard went on to become the first professor of clinical psychology at Ohio State University, like the University of Pennsylvania an important early training center in the field (Routh, 1994).

Lewis M. Terman (1877–1956) at Stanford University developed a standardized version of Binet's test, collected normative data for it, and introduced certain refinements such as the ratio IQ score (originally suggested by Wilhelm Stern of Hamburg). The 1916 Stanford-Binet, as it was called, dominated this field for many years. At about the same time, 1915, Robert Yerkes pointed out the unsuitability of the concept of mental age and of this testing format for use with adults and introduced his own 'point scale' as a substitute for it. Yerkes and his colleagues were also responsible for the development of group intelligence tests, the Army Alpha (for those who could read) and Army Beta (for the illiterate), used for mass testing of military recruits during World War I. Another wartime development was Robert S. Woodworth's Personal Data Sheet published in 1917. This was one of the first rationally developed self-report questionnaires intended to detect neurotic tendencies (Routh, 1994).

The Child Guidance Center Movement

The development of child guidance centers was another factor that influenced early clinical psychologists in the direction of working with children more than with adults. The first child guidance clinic was the Institute of Juvenile Research, established in 1909 by physician William Healy in conjunction with the juvenile court of Chicago. The idea behind such facilities was that careful clinical study of children engaging in antisocial activities could assist in guiding them away from crime. Healy was joined at first by clinical psychologist Grace Fernald and subsequently by her replacement, Augusta Bronner (Healy and Bronner, 1926). The child guidance clinic was the origin of the 'clinical team' of psychiatrist, psychologist, and social worker that later spread to other settings. The typical pattern was that the psychiatrist saw the child, the social worker saw the family, and the psychologist did the testing. The child guidance movement was supported by the Harkness family's philanthropy in the form of the Commonwealth Fund and replicated in many US cities and abroad.

The First Clinical Psychology Organization

In 1917, in Pittsburgh, a group of eight clinical psychologists organized themselves into what they called the American Association of Clinical Psychologists and invited 48 colleagues to join them (Routh, 1994). They were led by J.E.W. Wallin (1876–1969) and Leta Hollingworth (1886–1939). Incidentally, Hollingworth was the first to suggest in 1918 that a person trained in clinical psychology receive a distinctive type of degree, the doctor of psychology. The new organization was viewed by many as divisive and was soon incorporated into the American Psychological Association as its Clinical section. An effort by the same group to introduce procedures for certifying qualified clinical psychologists failed, however.

Psychometric Developments

The interwar years were a fertile time for the emergence of various new psychometric procedures, many of which continue to be in use today. For example, in 1921, the Swiss psychiatrist Herman Rorschach (1884–1922) published his well-known inkblot test. It was brought to the US by a child psychiatrist who taught it to a clinical psychology graduate student at Columbia named Samuel Beck (1896–1976). Beck then proceeded to do his dissertation on this new test and eventually to develop his own system for administering and scoring it. Psychologist Bruno Klopfer (1900–71), a disciple of Carl Jung (1875–1961), also introduced the Rorschach to the US and developed a separate system for administering and scoring it (*see* Projective Methods in Psychology). In 1936 the Thematic Apperception Test was introduced by Henry A. Murray (1893–1988) of the Harvard Psychological Clinic, and a colleague. Also in 1935 Edgar A. Doll (1889–1969), introduced the Vineland Social Maturity Scale, an interview-based method involving informants familiar with the person, for assessing the social competence of individuals suspected of mental retardation. David Wechsler (1896–1981) published the original version of his Wechsler-Bellevue intelligence test for adults. This was but the first of many Wechsler tests of intelligence and memory. It introduced the use of the deviation IQ, a standard score comparing the individual to age-matched normative subjects. In 1943, psychologist Starke R. Hathaway and psychiatrist J.C. McKinley introduced the first edition of the Minnesota Multiphasic Personality Inventory (MMPI). The MMPI had novel 'validity' indicators, and its measures of psychopathology were empirically keyed to psychiatrically defined groups (*see* Minnesota Multiphasic Personality Inventory).

Organizational Activities

In 1937 a new organization known as the American Association of Applied Psychology (AAAP) split off from the American Psychological Association (APA) to provide a home for various

professionally oriented groups including the clinical psychologists, who at this same time dissolved the Clinical Section of the APA. The AAAP began to publish the *Journal of Consulting Psychology*, which subsequently developed into a high-prestige clinical psychology journal (Routh, 1994).

It was also at this time that some preliminary developments in psychology began in other parts of North America. In 1937, for example, the first psychology curriculum was devised at UNAM, the National Autonomous University of Mexico, in Mexico City. In 1939, the Canadian Psychological Association was founded. It had 38 members to begin with, and it has been estimated that there were only 53 psychologists in all of Canada at the time. Needless to say, there were few prewar developments in Canada or Mexico specifically relating to clinical psychology.

The Post-World War II Boom in US Clinical Psychology

Clinical psychology expanded so greatly in the US after World War II that many brief historical accounts of the field even consider its development to have begun at that time. The war effort tended to draw everyone into it, either on the battlefield or on the home front. Many psychologists whose interests prior to the war had been strictly in research and in the academic side of the field found themselves assigned to carry out psychological testing or to help medical staff in treating psychiatric casualties. After the war, it was clear that the Veterans Administration (VA) would have to be vastly expanded to deal with the need for residential care, psychotherapy, or at least vocational counseling of some of those returning from military service.

In 1945, the VA and the newly established National Institute of Mental Health in the US came to the APA to ask it to establish a system for accrediting training programs in clinical psychology. The government intended to pour millions of dollars into training such individuals and needed to know which programs were competent to carry this out. In response, APA created a system of accreditation, and for the first time, it began to be possible to say who was a well trained clinical psychologist and who was not. David Shakow (1901–81) was the architect of the 1949 conference held in Boulder, Colorado, which ratified what has come to be called the 'scientist–practitioner' model of training clinical psychologists (Raimy, 1950) (*see* Training in Clinical Psychology in the United States: Scientist–Practitioner Model).

Postwar clinical psychologists continued in their role as mental testers, but gave more emphasis to the assessment of personality and psychopathology, not just cognitive status. This was the heyday of projective tests, and at least for a time the Rorschach inkblot was an appropriate symbol for the clinical practitioner of psychology. A well-known exemplar of the clinical psychologist as projective tester in this era was David.

Rapaport (1911–60), chief psychologist at the Menninger Clinic in Kansas. A two volume set of books published at this time by Rapaport and coworkers (Rapaport et al., 1945, 1946) established the Rorschach, the TAT, and the Wechsler test to be a 'full test battery' for almost a half century to come.

The clinical psychologists of this era were also eager to become full-fledged psychotherapists as well as mental testers. Their route to therapeutic training was blocked to some extent by the American Psychoanalytic Association's 1938 policy decision (contrary to Freud's own views) that only psychiatrists were to be trained in psychoanalysis. Clinical psychologists thus became very ingenious in devising ways of becoming therapists. The best known of them was perhaps Carl Rogers (1902–87), whose original therapy supervisor was the social worker Jessie Taft. Taft, in turn, had received her training from Otto Rank, a psychologist from Vienna who had received orthodox psychoanalytic training there and had been a close colleague of Freud's. Rogers was successfully assertive in other ways. At one point in his career he was director of a child guidance clinic when such administrative positions were supposed to be held only by physicians. Rogers also was determined to combine his psychology training with his role as a therapist. He was among the first to produce recordings of actual psychotherapy sessions, and was a pioneer in doing controlled research on the outcome of psychotherapy. Rogerian therapy ('client centered' or 'person centered', therapy, as it was later called) is still practiced and studied both in North America and elsewhere (Routh, 1994, 1998).

In 1945, the first state law certifying psychologists for independent practice was passed by Connecticut. By 1977, all states in the US had passed such certification or licensing laws regulating the use of the title, 'psychologist' or the practice of psychology (Routh, 1994).

The Behavior Therapy Movement

Some psychologists were of the opinion that clinical psychologists in their professional activities should not simply try to duplicate the activities of psychiatrists. In 1913, John Watson had boldly proclaimed a behavioristic approach to psychology, which was widely influential at least in academic psychology in the US. In a famous paper reporting research carried out under Watson's supervision, Jones (1924) described the case of 'Peter', whose fear of rabbits she desensitized. Not even Jones herself realized the wider implications of this study at the time, but in the light of events many years later some considered her to have been 'the mother of behavior therapy' (*see* Behavior Therapy: Psychiatric Perspectives).

The behavior therapy movement progressed not only by following its own agenda but by attacking its opponents. Psychologist Eysenck (1952) in England thus skeptically reviewed the evidence for the effectiveness of psychotherapy. It was not enough, he noted, to show simply that psychotherapy patients improved. One also needed to consider the rate of spontaneous improvement of patients who did not receive psychotherapy.

In 1962 in Charlottesville, Virginia, a behavior therapy conference was held, sponsored by psychiatrist Joseph Wolpe and psychologists Andrew Salter and Leo Reyna. At the time Wolpe had just published a book on his success in treating patients with phobias using the behavioral method of systematic desensitization. Soon afterward, Lang and Lazovik (1963) published the first controlled study of desensitization, in treating snake phobia. Soon the behavior therapy movement was in full swing, with its own organizations, journals, and many

adherents. Sidney Bijou and his colleagues established behavioral treatments based on the research of B.F. Skinner. These came to be known as applied behavior analysis and were especially influential in work with the behavior disorders of children and of those with mental retardation (*see* Behavior Analysis: Applied).

Canadian Clinical Psychology

It was in the 1960s that clinical psychology finally came of age in Canada. It was and is the largest applied specialty in psychology numerically in that country, as it is in the rest of the world. In 1965, the Couchiching Conference basically endorsed the 'Boulder model' of scientist–practitioner training for clinical psychology. Some Canadian doctoral programs such as the one at McGill even sought accreditation by the American Psychological Association. There was even something of a boom north of the border. It is said that by 1966, more than half the doctoral psychologists in Canada were either American born or trained in the US. In 1983, the Canadian Psychological Association established its own program of accreditation. The first CPA-accredited doctoral programs in clinical psychology were those at McGill, Concordia, and Simon Fraser Universities. The success of doctoral training in clinical psychology tells only part of the story there, however. In Quebec and some other eastern provinces, the master's degree was accepted as the entry level of training for independent clinical practice. By 1996, Canada had 88 graduate training programs in professional psychology (including clinical): 57 doctoral and 31 terminal masters.

Canadian clinical psychology is noted for particular strength in the area of neuropsychology, which built on Canadian strengths in the neurosciences, including the work of neurosurgeon Wilder Penfield at the Montreal Neurological Institute. In academic psychology, the research and writings of Donald Hebb concerning the CNS (conceptual nervous system) were influential. It was at McGill University that Olds and Milner published their famous 1954 paper on the reinforcement of an animal's behavior by electrical stimulation of its brain. On the clinical side, Ronald Melzack elaborated his theory of gating mechanisms influencing the experience of pain. Brenda Milner explored the role of the hippocampus in semantic memory, including work with her famous patient, 'H.M.' This man developed permanent memory deficits after surgery inadvertently destroyed his hippocampus bilaterally. Doreen Kimura documented the left cerebral hemisphere advantage in dichotic listening.

Clinical Psychology in Mexico

In 1997, the Division of Clinical Psychology of the APA held its midwinter board meeting in Mexico City, hosted by Juan Jose Sanchez-Sosa, the director of the school of psychology at UNAM, the National Autonomous University of Mexico. Sanchez-Sosa provided his US colleagues with a tour of this school, itself as large as many an entire college campus in the US. The school offers both Master's and PhD degrees in psychology, but as in much of Europe, these degrees are intended for those headed for academic and research careers. Those who intend to practice psychology, including clinical psychology, in Mexico need only a 'licentiate' or diploma to do so, which is awarded after 6 years of what to persons trained in the US seems to be undergraduate training. But students in such a program spend essentially full time on psychology, without the need for a broad liberal arts distribution of courses. This includes a significant amount of practicum experience. The psychology clinic, one of the practicum facilities used at UNAM, features a variety of clinical activities, including psychological testing, psychodynamic therapy, behavior therapy, group therapy, and even biofeedback. Since there is no certification or licensing system beyond the licentiate degree itself, it is difficult to be sure how many of these graduates are practicing clinical psychology in a way parallel to what would be seen in the US or Canada.

Independent Practice of Clinical Psychology

Although Lightner Witmer in his clinical work often collaborated with school teachers, physicians, or others, psychologists working in his clinic were never supervised by members of any other profession. This tradition of independent work has continued within the field of clinical psychology, somewhat in contrast with social work and nursing. The post-World War II expansion of the field in the US was primarily in the public sector, typically VA hospitals, but also child guidance centers and eventually community mental health centers. The large government training grants supporting clinical psychology programs at the time presupposed that the graduates would go to such public sector jobs or teach in colleges and universities. In the 1980s, the Reagan administration made most such training grants a thing of the past (Routh, 1994).

David Mitchell, a PhD student of Lightner Witmer, was one of the first individuals to make his living primarily in the private practice of psychology. Eventually, he was joined by many others. After all, the state and provincial laws that developed to regulate psychology after 1945 specified what qualifications were necessary to offer one's services to the public as a psychologist. Many psychologists trained in Boulder-model PhD programs did no research after graduation, and eventually the idea of training psychologists as practitioners rather than scientist–practitioners emerged. Beginning with the University of Illinois in 1966, a number of programs began to offer the doctor of psychology (Psy.D.) degree rather than the PhD The conference in Vail, Colorado in 1973 officially legitimized such practitioner training for the first time. In fact, a number of nonuniversity-affiliated schools of professional psychology sprang up beginning in the 1970s, many of them offering Psy.D. degrees. Often these programs were supported only by student tuition, and many students assumed substantial loans to finance their education (Routh, 1994). No such private school of professional psychology has emerged in Canada (nor in Mexico) (*see* Training in Clinical Psychology in the United States: Practitioner Model).

As psychologists in private practice emerged in larger numbers, they also became more active politically. The first practitioner became president of the APA in 1977, and within 20 years the first Psy.D. was elected to this position.

The practitioners began to dominate both the APA and the Canadian Psychological Association to a greater and greater extent. In response, many academic psychologists retreated to form national organizations of their own that were more research-oriented. Thus, the American Psychological Society was founded in 1988. Similarly, in 1989, academic and research psychologists in Canada founded the Canadian Society for Brain, Behavior, and Cognitive Science.

Practicing psychologists both in the US and Canada battled psychiatrists for their share of the mental health 'market.' Thus, they fought to obtain hospital privileges. They supported 'freedom of choice' legislation to become eligible as health providers reimbursable by health insurance companies and Health Maintenance Organizations. In 1988, a law suit by clinical psychologist Bryant Welch and others forced the American Psychoanalytic Association to begin to admit psychologists for training at its local institutes (Routh, 1994). Most recently, a number of practicing psychologists in the US, led by Patrick DeLeon, have been trying to obtain the right to prescribe medications for mental health conditions, so far without much success.

The Continued Commitment of Clinical Psychology to Research

Well before the founding of Witmer's clinic, there was a strong interest on the part of psychology in research on psychopathology, including its diagnosis and treatment. This continues to be the case. In fact, psychologists are far more likely than psychiatrists or those in other fields to be principal investigators on research grants from the National Institute of Mental Health. Such research is international in scope and is a collaborative interdisciplinary enterprise. The turf battles that characterize the marketplace of practice are much less typical in the research arena, where clinical psychologists often cooperate smoothly with experimental psychologists and statisticians as well as with medical colleagues. In research, it is neither possible nor necessary to draw any bright line to show the boundaries between these fields.

The diversity of such research is so great that it would be impossible to cover it in an article as brief as this one. Instead, a few examples must suffice. In 1954, psychologist Evelyn Hooker received her first NIMH grant to study homosexuality. Her work, much of it using the types of projective testing that were typical of clinical psychological work at the time, suggested that homosexuals might be essentially normal psychologically. This research was related to the later decisions to delete homosexuality as a pathological category from the Diagnostic and Statistical Manual of the APA.

In the 1950s, psychologist Leonard Eron began collecting peer-rating data on aggressive behavior in 8-year-old children. The subsequent longitudinal research he and his colleagues did helped establish the fact that aggressive behavior is highly stable well into adulthood. Psychologist Gerald R. Patterson studied aggressive behavior in children using direct behavioral observations, relating it to coercive processes in the parent–child dyad and doing controlled intervention studies showing how it could be reduced.

In the late 1950s, psychologist C. Keith Conners devised a simple teacher rating scale for the assessment of varied types of disordered behavior in school children. Together with child psychiatrist Leon Eisenberg he helped carry out the first controlled studies of the effects of stimulant medications on children's disruptive behavior (Conners and Eisenberg, 1963). Such research formed an important basis of present concepts of Attention Deficit Hyperactivity Disorder, the most commonly diagnosed type of child psychopathology and one still typically treated with stimulant medications. By the 1970s, Thomas Achenbach and his colleagues had begun to develop the use of parent, teacher, and self-ratings for child behavior into the most widely used forms of assessment by mental health workers.

In 1962, Meehl published a classic paper on 'schizo-taxia, schizotypy, and schizophrenia,' elaborating his concepts as to how genetic factors might be involved in the development of this disorder (Meehl, 1962). In 1973, psychologist Holzman and coworkers announced their discovery of smooth pursuit eye-movement difficulties in patients with schizophrenia (Holzman et al., 1973). This neurological symptom proved to be an important 'trait' marker in the first degree relatives of schizophrenics as well, whether or not they manifested any overt psychopathology. In Denmark, psychologist Sarnoff A. Mednick carried out a series of studies using the excellent public registers that characterize that country to do longitudinal, epidemiological studies of schizophrenia, implementing the type of research that Meehl had only been able to imagine.

Problems of the dysregulation of affect and emotion are the most ancient in the field of psychopathology, having been with us since Hippocrates. Beginning in the 1960s, psychologist Richard Lazarus elaborated his concepts of stress, appraisal, and coping and demonstrated experimentally how his subjects' use of different coping strategies could dampen or heighten their physiological stress (Lazarus, 1966). Beginning in the 1970s, Charles Spielberger and his colleagues began the development and validation of measures of state as well as trait anxiety and later of state and trait anger as well. In the 1970s, Martin E.P. Seligman and his colleagues showed how his studies of learned helplessness in dogs could be used to reconceptualize human depression.

In conclusion, clinical psychology has both international and important North American roots. In its first century, it has developed into a viable science and profession, and there is good reason to suppose that its trajectory will continue in the twenty-first century.

Clinical Psychology, Psychiatry and Homosexuality

Frank Muscarella, Barry University, Miami Shores, FL, USA

Abstract

The modern concept of homosexuality as a sexual orientation emerged with the field of descriptive psychiatry in Europe in the late 1800s. It was formally classified as a mental disorder in 1886 with its inclusion in *Psychopathia Sexualis*. Pressure from new research on homosexuality, public advocacy, and criticism of the earlier versions of the psychiatric diagnostic system resulted in its declassification in 1973. Major areas of current research in homosexuality include sexual orientation change efforts, the prevalence of depression and anxiety in homosexual men and women secondary to social stigma and prejudice, and theories on the etiology of homosexuality.

Introduction

The term homosexuality refers to a specific sexual orientation and is the integrated sexual, emotional, and psychological attraction to individuals of the same sex (Ellis and Mitchell, 2000). Today, homosexuality per se is not categorized as a mental disorder in the major psychiatric diagnostic classification systems that are used for the majority of the world's population: the American Psychiatric Association's (APA) *Diagnostic and Statistical Manual* (5th ed.) (*DSM-5*) (APA, 2013); the 2010 version of the World Health Organization's (WHO) *International Classification of Diseases* (ICD-10) (WHO, 2010); and the Chinese Classification of Mental Disorders (3rd ed.) (CCMD-3) (Lee, 2001; Wu, 2003). Rather, in Western culture, homosexuality is considered a normal variation in human sexuality (Drescher, 2010; Lee, 2001). However, homosexuality has been categorized as a mental disorder in the recent past, and presently across the world it is viewed with varying levels of intolerance that too often leads to harassment and persecution (Hadler, 2012; Reading and Rubin, 2011). Despite the fact that homosexuality has been declassified as a mental disorder, current psychotherapeutic approaches designed to change homosexual orientation to heterosexual orientation are based on the assumption that homosexual orientation is pathological (Drescher, 1998; Flentje et al., 2013; Gonsiorek, 2004; Grace, 2008).

Disagreement about the conceptualization of homosexuality as inherently pathological has existed since homosexuality first came under the scrutiny of the emerging field of descriptive psychiatry in Europe in the mid-1800s (De Block and Adriaens, 2013). Critics of the psychiatric diagnostic system argue that it too often serves as a culturally approved method to pathologize, control, and sometimes punish (cf Silverstein, 2008) socially unacceptable behavior that is more accurately described as nonconforming rather than pathological (Conrad and Angell, 2004). As such, the determination of pathology has been interpreted as partly a political process which, throughout the history of the development of the European and American psychiatric diagnostic frameworks, has resulted in socially unacceptable sexual behavior being consistently labeled as pathological and targeted for treatment and cure (De Block and Adriaens, 2013; Silverstein, 2008). There is no better example of this pathologizing and political process than the history of homosexuality in European and American psychiatry, the outcomes of which were ultimately exported to the world through readily adopted diagnostic classification systems (e.g., Lee, 2001; Mendelson, 2003).

Early History

Homosexual expression has been documented in cultures across the world and across recorded history; and cultural beliefs about it and responses to it have ranged dramatically from negative to positive (Crompton, 2003; Greenberg, 1988). Specifically, the conceptualization of homosexuality in Western culture has changed radically across historical periods. Ancient Greek and Roman cultures are considered the foundation of Western civilization. Homosexual behavior was common among and appreciated by the Ancient Greeks and Romans, and even their Gods engaged in homosexual behavior (Boswell, 1980, 1994; Cantarella, 1992; Dover, 1978). The consensus among historians is that the Ancient Greeks and Romans did not define people in terms of their sexual orientation, rather they described people in terms of the roles that they played in sexual interactions and the preferences they had for sexual partners. Social disapproval resulted not from the sex of the partner but from violations in sexual role (Cantarella, 1992; Dover, 1978). The other ancient European lands were made up of numerous cultures and there is very little documented evidence of their attitudes about homosexual expression. It appears from the few, mainly ancient Roman reports (e.g., Boswell, 1994; Tacitus, 2009), that attitudes in those cultures ranged from negative to positive, depending on the culture and the circumstances.

According to Boswell (1980, 1994), the advent of Christianity in Europe initiated a homogenization of societal attitudes, and consequently rules, toward sex. According to natural law, the only sex that was acceptable was between a husband and wife for procreation. Nonprocreative sexual acts were considered particularly sinful, but the Church in practice was relatively tolerant of unacceptable or 'deviant' sexual acts until around the AD 1200s. At that time, due to social change and perceived threats, the Church embraced orthodoxy with a concomitant intolerance and discouragement of nonprocreative sexual behavior, and in particular, homosexual behavior.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.21026-X

Crompton (2003) disagrees with Boswell and argues that from its inception, Christianity, for reasons that remain unclear, was extremely hostile toward homosexuality. The hostility worsened in terms of condemnation, persecution, and punishment with Christianity's development and spread across Europe and the world. Crompton states that Christianity emphasized and magnified the association of the biblical story of the destruction of Sodom with homosexuality. According to Crompton, Christianity's strongly negative conceptualization of homosexuality and the persecution that followed this, arose from the close association of homosexuality with the belief in God's anger against it and resulting disasters. Finally, he argues that this intense hostility manifested itself both in ecclesiastical laws against homosexual conduct and cruel punishments for it. As the ancient European lands developed into the modern European countries, ecclesiastical law and its penalties for homosexual acts were incorporated into civil law with the same strength of negative attitudes and responses and ultimately exported to the United States and across much of the world (e.g., Fradella, 2002).

The Mid-1800s

The definition of sexual deviance, including homosexual conduct, remained in the realm of moral, legal, and theological considerations until the mid-1800s with the advent of descriptive psychiatry (De Block and Adriaens, 2013). In the mid-1800s, across much of Europe, there was very severe criminalization of homosexual conduct, and some psychiatrists and early sexologists saw this as unjust and attempted social action (Conrad and Angell, 2004; De Block and Adriaens, 2013; Drescher, 2010). Critics from both fields found common ground and argued that people who engaged in homosexual conduct did so due to an innate, congenital condition and therefore punishment was not the appropriate social response.

The innate characteristic argument set the stage for the development of the concept of homosexuality as a condition that people could be identified as having. However, there were two different lines of reasoning about the meaning of the innate quality of homosexuality. Sexologists, including some physicians and psychiatrists, argued that not only was homosexuality a congenital condition but as such, it was part of the natural variation in sexuality and not inherently pathological or a social problem. Therefore, they argued that it should be decriminalized (Conrad and Angell, 2004; De Block and Adriaens, 2013; Drescher, 2010; Scasta, 1998). In fact, the modern term 'homosexuality' was coined in 1869 by a Hungarian journalist and social activist, K.M. Kertbeny (born Benkert) as part of his treatise against Paragraph 143, a Prussian law criminalizing homosexual conduct (Conrad and Angell, 2004; Drescher, 2010). Psychiatry, on the other hand, argued that homosexuality was congenital but pathological. Thus, homosexuality became a topic of interest in psychiatry, with the goal of bringing it into the medical realm for the 'humane' purpose of treatment and cure (Conrad and Angell, 2004; De Block and Adriaens, 2013; Drescher, 2010; Scasta, 1998). The psychiatric conceptualization soon dominated, introduced homosexuality into Western psychiatric nosology, and maintained its dominance through most of the twentieth century (Mendelson, 2003).

The Late 1800s

De Block and Adriaens (2013) report that in the mid-1800s both the general public and civil authority quickly turned to psychiatry for guidance in the determination of normal and deviant sexuality. Psychiatry's influence increased significantly by the late 1800s. One of the most influential books in psychiatry related to sexual deviance was first published in 1886 by the forensic psychiatrist Richard Von Krafft-Ebing: *Psychopathia Sexualis*. It contained three major groupings of sexual perversions, one of which included homosexuality. Although Krafft-Ebing used the terminology coined by Kertbeny, he did not adopt his conceptualization of it as normal variation. In fact, homosexuality was described as a degenerative disorder (Drescher, 2010). This initiated the formal psychiatric conceptualization and categorization of homosexuality as a mental disorder, and it remained as such until 1973 when the American Psychiatric Association declassified homosexuality as a mental disorder.

The development of the term 'homosexuality' and psychiatry's interest in it set the stage for a major cultural shift in focus from an act that was considered criminal to a sexual orientation and state of mind considered to be pathological. Boswell states that most historians agree that "…no Western legal or moral tradition – civil or ecclesiastical, European, English, or Anglo-American – has ever attempted to penalize or stigmatize a 'homosexual person' apart from the commission of external acts" (Boswell, 1993: p. 40 cited in Fradella, 2002: p. 280). However, the conceptualization of homosexuality as a mental disorder did contribute to the stigmatization of homosexual people (Silverstein, 2008). The understanding of and response to homosexuality moved across history from the theological to the legal to the psychiatric, but the strongly negative cultural attitudes about homosexuality remained relatively unchanged. This is best illustrated by the fact that although there was a change in the conceptualization of homosexual acts, and ultimately homosexuality, from sin to crime to mental illness, society's responses to homosexual behavior and homosexuality remained punitive and socially and personally destructive for those categorized as homosexual (Berube, 1990; Conrad and Angell, 2004; Crompton, 2003; Scasta, 1998; Silverstein, 2008).

The Early 1900s

Although *Psychopathia Sexualis* and the dominance of psychiatry formalized homosexuality as a mental disorder in the late 1800s, sexologists and social activists continued to press their point that homosexuality was not inherently pathological or a social problem, to smaller audiences. This disagreement about its conceptualization is best illustrated by the opinion of Sigmund Freud himself whose thinking was influenced by the work of sexologists (De Block and Adriaens, 2013). In 1903 the newspaper *Die Zeit* published an interview with Freud in which he stated "I am…of the firm conviction that homosexuals must not be treated as sick people…Homosexual persons are not sick. They also do not belong in a court of law!" (cited in Isay, 1989: p. 3).

De Block and Adriaens (2013) indicate that in the twentieth century in Europe and the United States two voices continued to

speak about homosexuality: psychiatry and sexology. Psychiatry maintained the pathology model. Sexologists, who included anthropologists, biologists, historians, sociologists, and physicians, became stronger and more well-defined in their approach. Sexologists brought to bear cross-species, cross-cultural, and historical research, as well as observations of essentially normal populations. The sexologists argued more forcefully, with new evidence in hand, that deviations from the sexual norm, such as homosexuality, were neither pathological nor dangerous to society, and they promoted social change in attitudes toward homosexuality. Again, their influence is expressed by Freud. In the famous letter to the mother of a homosexual man written in 1935, Freud stated: "Homosexuality is assuredly no advantage, but it is nothing to be ashamed of, no vice, no degradation; it cannot be classified as an illness; we consider it to be a variation of the sexual function, produced by a certain arrest of sexual development" (Freud, 1935/1960a: p. 423, cited in De Block and Adriaens, 2013: p. 283).

The Mid-1900s

American Psychoanalytic Influence

The prevailing voice regarding homosexuality remained that of mainstream psychiatry that held to the pathology perspective. This group was largely psychoanalytic and even though Freud himself did not see homosexuality as inherently pathological, after Freud's death in 1938, his followers became increasingly strident in their opinion that it was (Drescher, 1998). They based their study of homosexuality on the patients they saw in their private and institutional clinical practices (De Block and Adriaens, 2013; Silverstein, 2008). By contrast, one of the reasons that dissenting professionals disagreed with the classification of homosexuality as a mental disorder was that they saw people who were homosexual who lived essentially normal, contented lives. They recognized that although there could be psychopathology in homosexuals, a state of homosexuality was not inherently pathological itself. Freud himself had urged mental health professionals to take a wide perspective on homosexuals, specifically those who did not seek treatment: "If we disregard the patients we come across in our medical practice, and cast our eyes round a wider horizon, we shall come in two directions upon facts which make it impossible to regard inversion as a degeneracy:…" (Freud, 1962: p. 5).

However, other social forces appear to have contributed to some psychoanalysts' commitment to the pathological view of homosexuality. Isay (1989) reports that from its inception as a radical movement, psychoanalysis tended to be conservative, but on the topic of homosexuality it was the most conservative of all the mental-health professions. Isay states that although this is not a uniquely American phenomenon, this attitude is the most fixed in the American psychoanalytic tradition for two reasons.

The first reason is that during World War II (WW II), many analysts held important positions in the US military (cf Berube, 1990). Upon their return after the war they assumed positions of leadership in departments of psychiatry. They were very motivated to link psychoanalysis to medicine and to the disease model, to increase the prestige and influence of psychoanalysis and economic benefit to its members. The second reason is that shortly before the outbreak of WW II many European analysts fled to the United States. They were anxious about their professional and economic situation and quickly gravitated toward the movement to link psychoanalysis with medicine and the disease model to give stability and prestige to the profession. The McCarthy era followed WW II in the early 1950s in the United States. The goal of McCarthy and his adherents was to identify and remove from public life and influence communists, homosexuals, and other nonconforming 'enemies' of the United States. Many psychoanalysts, themselves recent arrivals to the United States, felt vulnerable and fearful and again gravitated to established and conforming professional organizations and doctrine (Isay, 1989). Some critics have also suggested that since psychoanalysts argued that the only effective cure for homosexuality was long-term psychoanalysis, the issue of secondary gain in their adherence to the disease model of homosexuality is open to question (e.g., Silverstein, 2008).

The DSM

The American Psychiatric Association, dominated by psychoanalytic psychiatrists, standardized the psychiatric classification system begun by the Army in 1945 (Berube, 1990), with the creation and publication of the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM*). The predecessor of the first edition of the *DSM*, the *Statistical Manual*, and the first edition of the *DSM* (1952) were relatively ambiguous about classifying sexual deviations as mental disorders (De Block and Adriaens, 2013). Although the first edition in 1952 said relatively little about homosexuality, it was classified as a 'sociopathic personality disturbance' that was part of a general category of personality disorders (De Block and Adriaens, 2013; Drescher, 2010). Reportedly, it was possible to diagnose even a contented homosexual as a sociopath because sociopathy was interpreted as a type of personality disorder characterized by a lack of distress or anxiety associated with the observed pathological condition (O'Donohue and Casselles, 2005 cited in Grace, 2008).

The DSM-II

De Block and Adriaens (2013) state that the *DSM-II* was an adapted version of the mental health disorder section of the World Health Organization's eighth *International Classification of Diseases* (*ICD-8*) which itself was an attempt to create a common ground for psychiatrists of different nationalities, institutional backgrounds, and theoretical orientations. In the first six printings (May 1968–October 1973) of the *DSM-II*, homosexuality was categorized unambiguously as a mental disorder (De Block and Adriaens, 2013); specifically, it was reclassified as a sexual deviation (Drescher, 2010). De Block and Adriaens (2013) report that this was the logical conclusion of a predominantly psychoanalytic body creating a classification system for mental disorders based on theory and etiology. That is, since the psychoanalytic theory held by this body stipulated that heterosexuality was the norm and that developmental trauma caused deviation from the norm, homosexuality could only be pathological (in contrast to Freud's thinking about the issue). However, it is argued here that the historically long negative religious and social

attitudes about homosexuality (Crompton, 2003) and the historically recent conditions in American psychoanalysis (Isay, 1989; Silverstein, 2008) must have had a combined effect that contributed to the resistance to a paradigm shift in the psychoanalytic profession. In fact, Drescher (1998) reports that post-Freud, psychoanalytic theories couched moral condemnation of homosexuality in scientific and pseudoscientific metaphors.

The Late 1900s

In the early 1970s, in the United States, there were a number of social forces that were developing, converging, and challenging the conceptualization of homosexuality as pathological. The voices of the sexologists and social activists, present since the beginning in the long discussion of homosexuality, became louder and stronger and appear to have made significant inroads into psychiatry. According to De Block and Adriaens (2013), shortly after the publication of the *DSM-II* in 1968, disagreement about the pathological conceptualization of homosexuality as well as other conditions, became more compelling in psychiatry. One factor influencing this disagreement was a new generation of scientifically trained psychiatrists who, seeing the benefits of psychotropic medications, began to question traditional psychoanalytic conceptualizations and wanted diagnostic categories that were data driven. The first two editions of the *DSM* had not included an explicit definition of mental disorder but, reportedly, relied on an implicit definition that included two criteria: distress and disability or functional impairment. However, most homosexuals exhibited neither, and if they did, an increasing number of mental health professionals understood that their problems resulted not from the state of being homosexual but rather from society's response to it. This realization logically led to the need to clarify the difference between socially unacceptable or deviant behavior and truly abnormal or pathological behavior (De Block and Adriaens, 2013).

Results from new research began to challenge the conceptualization of homosexuality as pathological. Kinsey's research published in 1948 and 1953 demonstrated that homosexual behavior was not the same as homosexuality since a large percentage of the population engaged in the behavior, and a larger percentage than believed had predominantly homosexual orientations. Chiang (2008) reports that Kinsey's work had a significant influence on psychiatrists' attitudes about homosexuality. For example, despite the antihomosexual fervor of the 1950s McCarthy era, the Group for the Advancement of Psychiatry, working with governmental agencies on a report about homosexuality, was relatively supportive of homosexuality. According to Chiang (2008), the report began by citing Kinsey's statistics of homosexual behavior in America and concluded that homosexuals functioned very well in civilian life and government settings, without problems; and suggested that investigations should be carried out on a case by case basis taking into account a variety of circumstances. Evelyn Hooker's (1957) ground-breaking study comparing the assessment results of heterosexual and homosexual men initiated an ongoing body of literature showing that there is no difference in psychological adjustment and functioning based on sexual orientation itself (Morin and Rothblum, 1991).

Another factor that contributed to a challenge of the status quo was a direct outcome of WW II (Berube, 1990). In the United States, many homosexual men and women served in the Armed Forces in WW II, and they served valiantly and effectively, often receiving military honors. They were pathologized by the mainstream of the military psychiatrists (mostly psychoanalytic), and some were persecuted and denied veterans' benefits after discharge. Individuals began to fight this discrimination themselves and with advocates in the veterans hospitals, military, and among local political representatives. After WW II there was an increase in the number of clinical psychologists due to the need to treat veterans. Chiang (2008) reports that clinical psychologists were less accepting than psychiatrists of the pathological view of homosexuality. After the war, many homosexual veterans, men and women, also chose to relocate to large urban areas to live their lives more freely rather than to return to small towns and rural areas and conform to local norms. All of this contributed to a change in their images of themselves from being pathological and victims, to being different but normal and political. This change set the stage for the postwar gay rights movement in the United States, which became a visible political force with the Stonewall riots in 1969. The movement was fueled by a younger generation, a cultural zeitgeist of liberation and antiauthority attitudes, and new research on homosexuality. This social movement confronted the establishment in psychiatry and psychology directly and forcefully, with new research and the devastating social and personal impact of the disease model (De Block and Adriaens, 2013; Drescher, 2010; Silverstein, 2008). The movement was particularly hostile and confrontational toward the psychoanalytic establishment because of its continued promulgation of the disease model and because of lingering resentment of its treatment of homosexual men and women in the Armed Services in WW II (Berube, 1990; Silverstein, 2008).

Declassification

In December 1973, after a long, raucous, and contentious battle with gay rights activists and their allies outside and within the discipline, the Board of Trustees of the APA unanimously accepted a proposal to remove homosexuality from the *DSM-II* (De Block and Adriaens, 2013; Drescher, 2010; Silverstein, 2008). Later, in response to protests from a number of leading psychoanalysts, a referendum was held with 58% of the membership of the APA accepting the proposal and 37% voting against (Silverstein, 2008). Homosexuality was eliminated as a mental disorder in the seventh printing (July 1974) of the *DSM-II* (De Block and Adriaens, 2013). The American Psychological Association and the National Association of Social Workers publicly supported the resolution of the American Psychiatric Association shortly after it was passed (Silverstein, 2008).

Critics of the declassification of homosexuality as a mental disorder argued that the decision was largely a political one (De Block and Adriaens, 2013). It is undeniable that cultural, social, and political forces converged and contributed to the process to depathologize homosexuality, just as they did in the process to pathologize it. Within the socio-political context of Europe in 1886, homosexuality was essentially proclaimed a mental disorder by Krafft-Ebing in *Psychopathia Sexualis*. Homosexuality

was declassified as a mental disorder by popular vote within the socio-political context inhabited by the American Psychiatric Association in 1973. Neither process employed rigorous empirically based standards, and both processes were arguably more socio-political than scientific (cf Grace, 2008). The entire pathologizing–depathologizing issue is consistent with Bayer's (1981) interpretation that "The status of homosexuality is a political question, representing a historically rooted, socially determined choice regarding the ends of human sexuality" (cited in Drescher, 1998: p. 5).

Both processes supported the contention of critics that the psychiatric diagnostic system too often served as a vehicle to pathologize socially unacceptable behavior that was arguably not pathological (Conrad and Angell, 2004; Scasta, 1998; Silverstein, 2008). However, this scientifically questionable pathologizing-depathologizing of homosexuality led to three positive outcomes all present in the subsequent version of the *DSM*, the *DSM-III*: the development of a more data-driven diagnostic classification system; a clear distinction between a mental disorder and socially deviant behavior; and, most importantly, an explicit operational definition of the term 'mental disorder' was derived, which noted that subjective distress and functional impairment were essential features of this condition (De Block and Adriaens, 2013). Further, De Block and Adriaens argue that the reconceptualization of homosexuality was an essential component for the development of the definition of mental disorder, and this has reverberated across proposed diagnostic categories through all subsequent versions of the *DSM*.

Although homosexuality per se was deleted from the *DSM-II*, another, related disorder was added under the diagnostic category 'Sexual Deviations'. A reading of the eleventh printing (January 1978) of the *DSM-II* (APA, 1968) describes "Sexual orientation disturbance [Homosexuality]" as follows: "This is for individuals whose sexual interests are directed primarily toward people of the same sex and who are either disturbed by, in conflict with, or wish to change their sexual orientation. This diagnostic category is distinguished from homosexuality, which by itself does not constitute a psychiatric disorder" (p. 44).

Subsequent Editions of the DSM

The *DSM-III* (APA, 1980) included an explicit conceptualization of a mental disorder. Parenthetically, the relationship between a mental disorder and socially deviant behavior was clarified: ("When the disturbance is *limited* to a conflict between an individual and society, this may represent social deviance, which may or may not be commendable, but is not by itself a mental disorder") (p. 6). This clarification has run through the later editions of the *DSM*. The DSM-5 (APA, 2013) is more explicit: "Socially deviant behavior (e.g., political, religious, or sexual) and conflicts that are primarily between the individual and society are not mental disorders unless the deviance or conflict results from a dysfunction in the individual, as described above" (p. 20).

The *DSM-III* did not include homosexuality as a mental disorder, but it did include a reformatting of the *DSM-II* sexual orientation disturbance with the new diagnostic category of 'Ego-dystonic Homosexuality' listed in a section titled 'Other Psychosexual Disorders'. This comprised people who had little to no heterosexual interest and experienced homosexual arousal that was unwanted and distressing. This diagnostic category appeared to ignore the fact that distress about one's homosexual orientation was the result of social stigmatization, and this caused distress, not homosexuality itself. This diagnostic category was greeted with great disapproval, rarely used, and eliminated in the revision, *DSM-III-R* (APA, 1987) (De Block and Adriaens, 2013; Drescher, 2010; Silverstein, 2008). However, the association between homosexuality and a mental disorder continued to exist, albeit in a very subtle way. The *DSM-III-R* included the diagnostic category 'Sexual Disorder Not Otherwise Specified' listed in a section titled 'Other Sexual Disorders'. This could cover a number of conditions but included the explicit example of persistent distress over sexual orientation. The number of heterosexuals who complained of this appears to have been zero. This category remained in the *DSM-IV* (APA, 1994) and in the *DSM-IV-TM* (APA, 2000) in a section titled 'Sexual and Gender Identity Disorders'. The *DSM-5* (APA, 2013) does not contain the category and distress about sexual orientation is not described. The slow exit of the association of homosexuality with mental disorder appears to have been due to the lingering effects of psychoanalytic interpretations (Conrad and Angell, 2004; De Block and Adriaens, 2013; Drescher, 2010; Mendelson, 2003; Silverstein, 2008).

Under the *DSM-5*, should debilitating distress about sexual orientation occur in an individual, it could be listed under the diagnostic category of 'Unspecified Mental Disorder' which reads as follows: "This category applies to presentations in which symptoms characteristic of a mental disorder that cause clinically significant distress or impairment in social, occupational, or other important areas of functioning predominate but do not meet the full criteria for any mental disorder" (p. 708). In theory, this diagnostic category would allow a clinician to acknowledge a clinically relevant degree of distress and impairment due to one's sexual orientation without any implication that it is the orientation itself that is responsible for the distress. Thus, it appears that the *DSM-5* has completely severed the association between homosexuality and mental disorder, 127 years after its first appearance in *Psychopathia Sexualis*.

Other Psychiatric Classification Systems

The World Health Organization's International Classification of Diseases *ICD-10*, published in 1992, removed the diagnostic category 'homosexuality' (Mendelson, 2003), but added some other categories. The 2010 version of the *ICD-10* (WHO, 2010) has a general category (F66) titled "Psychological and Behavioural Disorders Associataed with Sexual Development and Orientation". It is specified that "Sexual orientation by itself is not to be regarded as a disorder". It then lists the following diagnoses: sexual maturation disorder, egodystonic sexual orientation, sexual relationship disorder, other psychosexual development disorders and psychosexual development disorder, unspecified. 'Sexual maturation disorder' is a term that can be applied to those who experience anxiety or depression because of their gender identity or sexual orientation, and is most applicable to adolescents. Egodystonic sexual orientation is the term for those who are distressed by their gender identity or sexual orientation and want to change it. Sexual relationship disorder is the term for those whose gender identity or sexual

orientation is responsible for difficulties in developing or maintaining a relationship with a sexual partner.

It appears that classification in the *DSM-5* is more evolved than that in the *ICD-10* in several ways: the *DSM* separates sexual orientation from gender identity, and it has done away with explicit diagnostic categorization of distress related to sexual orientation. As has been reviewed, essentially distress occurs only in cases of a homosexual orientation, and it is an accepted fact that this problem results from social stigma, not from the orientation itself. It has been argued that the presentation of sexual orientation in the *ICD-10* should be revised (Mendelson, 2003).

The Chinese Classification of Mental Disorders (3rd ed.) (*CCMD-3*) is used in China, which contains 20% of the world's population. The *CCMD-3*, published in 2001, has been heavily influenced by the *DSM* and the *ICD*, but incorporates elements unique to Chinese culture (Lee, 2001). The third edition dropped the diagnostic category of 'homosexuality' but added 'ego-dystonic homosexuality' (Wu, 2003). More specifically, Lee (2001) reports that despite an understanding that homosexuality is considered a normal variant in the Western world, exclusive homosexuality is considered a mental disorder, but only if it causes distress and a desire to change it. Lee states that it is not clear why heterosexuals who are distressed with their sexual orientation are not considered mentally ill. His interpretation is that the Chinese psychiatric establishment is going through a step-by-step paradigm shift similar to that experienced by the American psychiatric establishment.

Contemporary Issues in Research

The subject of homosexuality generates a considerable amount of research from a variety of perspectives. Three major areas are considered here. These are the outcomes of sexual orientation change efforts, the prevalence and causes of mental illness in homosexual men and women, and theories on the etiology of homosexuality.

Sexual Orientation Change Efforts

Therapies known as conversion therapy, reparative therapy, and sexual reorientation are collectively referred to as sexual orientation change efforts (SOCE). According to Drescher (1998), despite the declassification of homosexuality by the APA in 1973, a small group of conservative psychoanalysts maintained that homosexuality was indeed a pathological condition and a homosexual orientation could be changed to heterosexual orientation. SOCE were linked primarily to psychodynamic and behavioral theories in the 1960s and 1970s (Flentje et al., 2013). SOCE today do not appear to have close association with any psychological theory. However, they do appear to be the direct descendants of earlier psychoanalytic change efforts that have been adopted and modified by some fundamentalist Christian groups (Drescher, 1998). Currently, the change therapies use a group of verbal interventions that essentially discourage homosexuality and encourage heterosexuality (Flentje et al., 2013). Most of the individuals who seek out such treatment are those who are having problems reconciling their fundamentalist Christian faith with their homosexual orientation (Drescher, 1998; Flentje et al., 2013; Gonsiorek, 2004; Grace, 2008). Some of these individuals are minors who have been forced into therapy by their parents.

SOCE have come under scrutiny and criticism. It has been argued that behavioral science and the psychological techniques derived from it are not good to help people reconcile issues of religious doctrine, because of the inherent conflict between faith and science regarding the source of truth (Gonsiorek, 2004; Grace, 2008). Major mental health organizations in the United States including the American Psychiatric Association, the American Psychological Association, and the National Association of Social Workers have all made policy statements rejecting SOCE (Flentje et al., 2013; Grace, 2008). Half a century of research on SOCE has not shown that they work. The American Psychological Association has stated that there is no demonstrated evidence that SOCE are effective and there is some evidence that they may cause harm (Hancock et al., 2012). Relying partly on this argument, both the states of California and New Jersey passed laws in 2013 banning the use of SOCE for individuals under the age of 18.

Homosexuality and Mental Illness

Although homosexuality is not a mental disorder, the evidence suggests that homosexual adolescents (Mustanski and Liu, 2013) and men and women (Cochran et al., 2003) may be more vulnerable than their heterosexual counterparts to some forms of mental illness such as anxiety and depression. An enormous body of psychological research, beginning with Evelyn Hooker (1957) and up to the present, has consistently shown that there are no psychological differences between people based on sexual orientation alone; and when differences do occur they are the result of society's response to homosexuality, not of homosexuality itself. Research indicates that differences in psychological functioning that do exist between homosexuals and heterosexuals result from the stress associated with the societal pressures on homosexuals as a marginalized group (Grace, 2008; Meyer, 2013).

Homosexual men and women across the world live under varying levels of social marginalization and intolerance that lead to varying levels of aggression against them (Hadler, 2012; Reading and Rubin, 2011; Meyer, 2013; Sue, 2010). Western countries have the lowest levels of gross aggression toward homosexual men and women and greater tolerance (Hadler, 2012; Reading and Rubin, 2011). However, even in Western countries, homosexual men and women, like individuals of many socially marginalized groups, are more likely to suffer from an accumulation of microaggressions in daily life (Sue, 2010). Microaggressions are verbal, behavioral, and environmental insults that communicate hostility, dislike, and disdain and are detrimental to psychological and physical well-being. Meyer (2013) conducted meta-analyses and found that homosexual men and women have a higher prevalence of mental disorders than do heterosexuals. He attributes this to what is termed 'minority stress' or the stress of living as a minority group suffering from stigma and social prejudice. Stigma and prejudice generate micoaggressions (Sue, 2010). Meyer recommends that interventions at both the personal level (e.g., improving individual coping methods) and the structural level (e.g., changing oppressive social and legal

policies) may be useful in alleviating minority stress. Consistent with Meyer's observation, research has shown that socializing agents such as laws affect the individual's attitudes toward homosexuality with more legal protection of homosexuality contributing to greater acceptance (van den Akker et al., 2013).

Theories on the Etiology of Homosexuality

At this time, it is not scientifically known how a particular sexual orientation develops nor can deviation from heterosexual orientation development be reliably predicted. The consensus among most of the scientific community is that sexual orientation develops in an individual as the result of an interaction between genetic, biological, developmental, psychological, cultural, and unique experiential factors. However, there are a number of theories on the development of homosexual orientation. These share the implicit assumption that sexual orientation development would be expected to be heterosexual or fall on a continuum from heterosexual to bisexual because of the direct relationship of these orientations to reproduction. Because exclusive homosexuality is not directly associated with reproduction, its prevalence has generated interest in its possible origins. Comprehensive reviews and critiques of the theories on the etiology of homosexuality are presented by Rosario and Schrimshaw (2014) and LeVay (2011). Muscarella (2006) presents a review of evolutionary theories. A summary of all of these theories follows.

The theories on the etiology of homosexuality have emerged historically with the predominant scientific paradigms that developed across time and were applied to human sexuality. The major contemporary theories of the etiology of homosexuality begin with Freud in his psychoanalytic theory. He theorized that homosexuality in males was one possible product of an unresolved oedipal complex, in which a boy failed to identify with his father. In the little he wrote about female homosexuality, its origins appear to be due, not to an unresolved Electra complex, but rather to a later turning away from the father because of anger and disappointment. The behavioral theories attribute the development of homosexual orientation to learning and the result of classical and operant conditioning. The advent of research on prenatal hormonal influences on the development of brain organization and sexual behavior in nonhuman animals led to a number of neurohormonal theories. These hold that various factors may disrupt the normal level of prenatal hormones during gestation, resulting in the organization of the brain for homosexual orientation. The "exotic becomes erotic" model by Bem includes both neurohormonal and social factors. Bem theorizes that males and females exhibit sex-typed behavior that makes them different from each other, or exotic; and across development, the exotic becomes sexually attractive or erotic. Prenatal hormonal variation causes some children to develop some gender-nonconforming behavior. Thus, the behavior of their own gender is exotic, and ultimately, they become attracted to members of their own gender.

The identification of genetically linked characteristics generated theories on the possibility of an inherited gene, or set of genes, that resulted in a homosexual orientation.

Since, in theory, these genes could not be passed on directly, other theories were developed to explain a possible process. These theories can be categorized as evolutionary theories because they try to explain how genes associated with a homosexual orientation would have been indirectly reproductively beneficial and thus selected for during human evolution (Muscarella, 2006). The first evolutionary theory was presented by E.O. Wilson who stated that among human ancestors, homosexual men and women may have held particularly high social positions such as the group shaman. This would have raised the status of their families who may have then reproduced more successfully as a result.

Edward Miller theorized that homosexuality is a polygenic trait that results from selection for a number of characteristics that each contribute to fitness. These include tenderness, empathy, and kindness which result from a more feminized brain, which would have made ancestral males more attractive to females as mates and better fathers. In some cases the brain organization is extremely feminized giving rise to a homosexual orientation. Miller uses the maternal immune hypothesis to explain the purported fraternal birth order effect, which holds that the probability of a male developing a homosexual orientation increases with the number of older brothers. The maternal immune hypothesis holds that mothers carry a 'biological memory' (in the form of an H–Y antigen) of the number of sons they have gestated that leads to changes in the intrauterine environment – and results in the feminization of later born males. According to Miller, younger sons, being more sensitive and flexible, would compete less with older brothers for resources. Homosexuality in males would be the rare by-product of genetic variability for the capacity to flexibly exploit various social niches, outweighing the cost of a few individuals who do not reproduce. Another line of research holds that maternally inherited factors are associated with both male homosexuality and increased fecundity in female relatives.

The alliance theory holds that during the course of human evolution, homosexual behavior may have reinforced alliances between same-sex conspecifics, which increased their chances of survival and reproduction (Muscarella, 2006). Thus, there was selection for homosexual behavior in all humans. Genetic variability underlying this behavior may result in individuals with a preference for exclusive homosexual behavior and ultimately the development of a homosexual orientation.

Simon LeVay (2011) looks at biological and psychological data and suggests a compelling neurohormonal theory for the development of homosexual orientation. He argues that homosexuality is a 'package' of mental traits, many of which are gender-atypical, while heterosexuality is a package of mental traits that are gender-typical. He states the association of gendered traits with sexual orientation arises from sexual differentiation of the brain under the influence of sex hormones. LeVay speculates that a number of social and biological factors across human history may have influenced prenatal hormonal conditions and may have influenced the prevalence of homosexuality over time. His theory complements evolutionary theories and could be interpreted as a proximate mechanism for variation in sexual orientation.

Summary and Conclusions

Homosexuality appears to have existed cross-culturally over recorded history. Societies' reactions to homosexuality have

ranged from negative to positive as functions of the historical and cultural traditions of each society. Christianity introduced a very negative view of homosexuality that remained relatively constant across history. With cultural evolution, the conceptualization of homosexuality changed from sin to crime to mental illness. The inclusion of homosexuality in *Psychopathia Sexualis* formally introduced homosexuality to the Western world as a mental disorder, and this conceptualization was then exported across the world and across generations in psychiatric diagnostic classification systems. Disagreement about the inherent pathology and social danger of homosexuality existed from the beginning of the conceptualization of homosexuality. However, it was not until the late twentieth century that research supporting this view was abundant and that Western society was culturally prepared to accept it and act upon it. Although the American Psychiatric Association declassified homosexuality as a mental disorder in the DSM-II in 1973, it is argued here, that it was not until 2013 with the publication of the DSM-5 that the final vestiges of the link between homosexuality and psychopathology finally vanished.

Despite the declassification of homosexuality as a mental disorder in the major psychiatric diagnostic classification systems of the world, some societies and subcultures continue to view it as a mental disorder and support 'treatments' to change it. This is clearly outside of mainstream psychiatry and psychology and more harmful than helpful. Research has also demonstrated that homosexual adolescents, men, and women tend to exhibit more mental disorders such as depression and anxiety as a result of the major and minor psychological stresses associated with stigma, prejudice, harassment, and in some cases persecution. Research shows that psychological interventions at the personal level can help individuals to cope with this minority stress and, consequently, to function more effectively. However, research also shows that interventions at the societal level aimed at changing socializing agents such as law and government policy can lead to more tolerant societies that generate less stress for homosexual men and women. Thus, for the purpose of attaining this goal, efforts to change the socializing agents in societies and subcultures oppressive to homosexual men and women are to be encouraged and supported. Finally, there are numerous theories on the etiology of homosexual orientation. They reflect the predominant paradigms of the times in which they developed. Currently, the neurohormonal and evolutionary theories provide a compelling rationale.

Abstract

Closed and open systems refer to whether organizational entities, such groups and organizations, are viewed as relatively closed or open to their environment. Such a perspective has a profound influence on how organizations are described and studied. When treated as closed systems, organizations are unaffected by their environment, and attention is directed inward to internal structures and behaviors. As open systems, organizations are interdependent with their environment, and focus is outward to how such interaction is managed. Knowledge of closed and open systems derives from the broad framework of general systems theory which seeks to explain the structure and behavior of complex wholes called systems. This article shows how general systems theory is applied to organizations. It describes the systemic properties of organizations as closed and open systems, and draws implications for how they are structured and managed.

Closed and open systems refer to whether organizational entities, such as groups and organizations, are viewed as relatively closed or open to their environment. Such a perspective has a profound influence on how organizations are described and studied. When treated as closed systems, organizations are unaffected by their environment, and attention is directed inward to internal structures and behaviors. As open systems, organizations are interdependent with their environment, and focus is outward to how such interaction is managed.

Knowledge of closed and open systems derives from the broad framework of general systems theory (GST) which seeks to explain the structure and behavior of complex wholes called systems (e.g., von Bertalanffy, 1956; Miller, 1978). This broad metatheory is based on related research from the physical, biological, and social sciences, and seeks to discover general laws which apply to all levels of systems from single cells to societies.

This article shows how GST applies to organizations. It describes the systemic properties of organizations as closed and open systems, and explains how they are structured and managed.

Organizations as Systems

Organizational scholars use GST to describe the general properties of organizational systems. This includes defining their constituent parts and how they are interrelated to form a system. It also involves identifying different levels of organizational systems and explaining how they interact with each other.

Organizational Parts, Relationships, and Wholes

A key premise of GST has to do with the definition of a system and how it forms an organized whole. A system is composed of parts and relationships among them. The system provides the framework or the organizing principle for structuring the parts and relationships into an organized whole. This makes systems capable of behaving in ways that are greater than merely the sum of the behaviors of their parts, thus leading to the common adage: "the whole is greater than the sum of its parts." Organizational scholars have expended considerable effort in identifying the constituent members or subunits of organizational systems and examining relationships among them. They have sought to discover the organizing principles through which the parts are arranged into a coherent whole. For example, job design researchers have identified different elements of jobs; they have shown how they can be combined to affect employee motivation. Group dynamics scholars have spent considerable time addressing issues of group membership and member interaction. They have discovered different ways of structuring groups to perform tasks that members could not do working alone. They have shown how, under certain conditions, groups can outperform individuals, thus leading to various high-performing group designs, such as self-managing teams, quality circles, and cross-functional teams. Similarly, organization theorists have identified the different components of organizations and examined relations among them. They have found different ways to organize the components and relationships for competitive advantage (Cummings and Worley, 2015).

Levels of Organizational Systems

A second principle of GST has to do with the multilevel nature of systems. Systems exist at different levels; the levels exhibit a hierarchical ordering, with a higher level of system being composed of systems at lower levels. For example, societies are composed of organizations; organizations are composed of groups; groups are composed of individuals; and so on. Higher-level systems provide constraints and opportunities for how a system organizes its parts, and the nature of those parts affects the system's organizing possibilities. Thus, to describe a system at a particular level and explain its behavior, it is necessary to look both upward to the higher level system

within which it is embedded and downward to its constituent parts.

This multilevel perspective has led scholars to identify different levels of organizational systems, and to focus on understanding them and how they interact with each other. Considerable attention has been directed at specifying appropriate levels of analysis, both for conceptualizing about organizational systems and for aggregating and disaggregating data that apply to different levels. For example, scholars have developed analytical guides for aggregating data from individuals to devise measures of group and organization functioning. As researchers have developed more comprehensive theories and more powerful analytical methods, they have made finer distinctions among levels of organizational systems, particularly above the organization level. This has led to at least five levels of organizational systems:

1. individual member, role, or job;
2. group;
3. organization;
4. population of organizations and/or alliance among organizations;
5. community of populations and/or community of alliances.

Organizations as Closed Systems

Closed systems do not interact with the environment, and consequently their behavior depends largely on the internal dynamics of their parts. They seek to maintain a steady state or equilibrium among their parts while performing goal-directed behaviors. Because the environment is inconsequential for goal achievement, system behavior is highly specified and maximally controlled within the system.

Until the late 1960s, organizational scholars tended to employ a closed-system perspective for studying organizations. Organizational environments were seen as relatively simple and predictable, and, thus, were not problematic or significant for how organizations behaved. Attention was directed at the internal dynamics of groups and organizations, particularly at how member behavior was controlled to achieve specific objectives and goals. This led to extensive knowledge of organizational control mechanisms and search for the best way to structure organizational systems. For example, at the individual level, job design researchers discovered how to analyze and maximally specify the most efficient way to perform various tasks. At the group level, researchers showed how group structures and processes could contribute to member conformity to group norms. At the organization level, scholars studied a variety of devices for controlling member behavior, such as managerial hierarchy, rules/procedures, and functional design.

Organizations as Open Systems

In the late 1960s, organizational scholars began to broaden their focus to external forces affecting organizational systems. This open systems view was fueled by growing applications of GST to the social sciences and by realization that the behavior of organizational systems could not be adequately explained without examining environmental relationships and their effects on the system (e.g., Aldrich, 1979; Buckley, 1967; Katz and Kahn, 1966; Lawrence and Lorsch, 1967, Scott and Davis, 2007; Thompson, 1967). It has led to considerable research about organizational environments, their dynamics and effects, and how organizational systems interact with them. An open systems perspective draws attention to how organizations exchange information and resources with their environment, and how the two mutually influence each other. Moreover, it provides a number of useful concepts for understanding how organizations maintain functional autonomy while influencing and adapting to external forces.

Critical Functions

To survive and prosper, open systems need to perform at least four critical functions:

1. transformation of inputs of energy and information to produce useful outputs;
2. transaction with the environment to obtain needed inputs and to dispose of outputs;
3. regulation of system behavior to achieve stable performance;
4. adaptation to changing conditions.

Because these different functions often place conflicting demands and tension on open systems, system viability depends on maintaining a dynamic balance among them. Organizational researchers have devoted considerable time identifying and explaining how these four functions operate and contribute to organizational survival and effectiveness. This has led to knowledge about how organizations and groups produce products and services through operating and developing different technologies; how they protect their technologies from external disruptions while acquiring raw materials and marketing finished products; how they regulate themselves for stable performances while initiating and implementing innovation and change. This research defines a key role of management in organizational systems as sustaining a dynamic balance among these four functions; one that allows the organization sufficient stability to operate rationally yet requisite flexibility to adapt to changing conditions.

Information and Resource Flows

As open systems, organizations seek to sustain a cycle of activities aimed at taking inputs of information and resources from the environment, transforming them into outputs of goods and services, and exporting them back to the environment. This cycle enables organizations to replenish themselves continually, so long as the environment provides sufficient inputs and the organization delivers valued outputs. Considerable research has gone into understanding how organizations manage these information and resource flows. One perspective focuses on how organizations process information to learn how to improve themselves and to relate to their environments. Organizations must be capable of learning from their experiences and of disseminating such knowledge widely if

they are to change themselves to respond to emerging conditions. Consequently, research has been directed at organizational learning and knowledge management, particularly at discovering mechanisms to enhance learning capability, such as shared databases, groupware, and decision-support systems. Another view concentrates on how organizations compete for resources through managing key resource dependencies. Attention has been directed at how organizations gain access to resources without becoming overly dependent on those who supply them. Still another perspective focuses on how organizations gain legitimacy from environmental institutions, so they can continue to function with external support. Researchers have sought to identify the institutional demands of powerful resource providers, and how organizations respond to them.

Boundaries

In managing information and resource flows, organizations, like all open systems, seek to establish boundaries around their activities. These organizational boundaries must be sufficiently permeable to permit necessary environmental exchange, yet afford the organization adequate protection from external demands to allow for rational operation (Santos and Eisenhardt, 2005). Organizational scholars have devoted considerable attention to understanding the dual nature of organizational boundaries. They have studied various boundary-spanning roles that relate the organization to its environment, such as sales, public relations, and purchasing. They have examined how organizational members perceive and make sense out of environmental input, and how organizational boundaries vary in sensitivity to external influences. Researchers have also identified different strategies for protecting transformation processes from external disruptions while remaining responsive to suppliers and customers.

Self-Regulation

Viewed as open systems, organizations use information about how they are performing to modify future behaviors. Referred to as cybernetics, this information feedback enables organizations to be self-regulating (e.g., Ashby, 1956). They can adjust their behavior to respond to deviations in expected performance. To be effective, however, organizations must have sufficient diversity of responses to match the variety of disturbances encountered. Thus, as technologies and environments become more complex and uncertain, organizations seek to become more flexible and nimble. They can enhance their adaptive capabilities through such innovations as downsizing, employee empowerment, and reengineering.

Extensive research has been devoted to understanding how organizations regulate themselves. Using modern information technology, organizations have developed a variety of methods for setting goals, obtaining information on goal achievement, and making necessary changes. For example, database technologies enable organizations to store large batches of information and to logically connect events, actions, and outcomes. Employees can access and revise this information through online, common databases.

Equifinality

As open systems, organizations display the property of equifinality. They can achieve objectives with varying inputs and in different ways. Consequently, there is no one best way to design and manage organizations, but there are a variety of ways to achieve effective performance. This contrasts sharply with a closed system perspective which seeks the one best way to structure and control organizations.

Organizational researchers have devoted considerable attention to identifying different choices for designing and managing organizations. This has led to a virtual revolution in new organizational designs aimed primarily at making organizations leaner, more flexible, and more responsive to human resources. For example, traditional bureaucratic structures that emphasize efficiency and control have increasingly been supplanted with designs that emphasize flexibility and innovation, such as matrix organizations, horizontal organizations, network organizations, and virtual organizations. Moreover, researchers have developed contingency theories which specify under what technological, environmental, and human conditions different organizational designs are likely to be most successful. For example, these newer, more innovative designs are best suited to situations where technologies are complex, environments are unpredictable, and people have high growth needs.

Promising Trends

Organizational researchers have recently applied systems concepts to understand how organizations can adapt to rapidly changing, unpredictable environments. They have borrowed heavily from complexity theory which seeks to explain the behaviors and changes that can occur when the parts of complex systems interact (e.g., Holland, 1995; Brown and Eisenhardt, 1998; Eisenhardt and Piezunka, 2011) in nonlinear and dynamic ways and can invent entirely new responses to external forces. These concepts provide a dynamic, change-oriented perspective on organizations. They help to explain how organizations can restructure themselves continually to keep pace with fast-changing environments.

Abstract

While cluster randomized trials (CRTs) have unique features that differentiate them from conventional (individually) randomized trials, standard research ethics guidelines by and large assume individual randomization. The Ottawa Statement on the Ethical Design and Conduct of Cluster Randomized Trials provides recommendations specific to CRTs to assist researchers and research ethics committees in the ethical design, conduct, and review of CRTs. In this article we describe the unique characteristics of CRTs, identify the main ethical issues raised, and discuss the application of the Ottawa Statement to CRTs in health, social, and behavioral research using a series of examples.

Introduction

Cluster randomized trials (CRTs), also known as place or group randomized trials, are an increasingly common research design in the areas of health services, public health, education, welfare, criminal justice, and international health and development research (Boruch et al., 2004; Donner and Klar, 2000; Murray, 1998). In CRTs, the individuals whose outcomes are of interest in the trial are randomized – not in the conventional way as independent individuals – but as naturally occurring groups or sites such as communities, housing developments, schools, or worksites. All individuals in a particular group (i.e., 'cluster') are allocated to the same study arm. It has become widely recognized that CRTs have unique methodological requirements because observations from multiple individuals in the same cluster are usually positively correlated; less well recognized is that CRTs also have unique implications for research ethics (Edwards et al., 1999; Hutton, 2001; Klar and Donner, 2007). Because these implications have not been explicitly addressed in major research ethics codes such as the Declaration of Helsinki (World Medical Association, 2008) and the International Ethical Guidelines for Biomedical Research Involving Human Subjects (Council of International Organizations of Medical Science (CIOMS), 2002), research ethics committees (RECs) and researchers have been left uncertain as to the best ethical practices in CRTs. The Ottawa Statement on the Ethical Design and Conduct of Cluster Randomized Trials (Weijer et al., 2012) was developed to address this gap. It was the end-product of a 5-year international collaboration (Taljaard et al., 2009), which included a series of empirical studies documenting ethical issues in CRTs (Chaudhry et al., 2013; McRae et al., 2013a,b; Taljaard et al., 2011, 2014a,b), a detailed ethical analysis rooted in ethical principles and international regulations (McRae et al., 2011a,b; Binik et al., 2011; Gallo et al., 2012), and a consensus process that included an international interdisciplinary expert panel to write ethics guidelines for CRTs (Weijer et al., 2012; Taljaard et al., 2013). In this article we describe the unique characteristics of CRTs, identify the main ethical issues raised, and discuss key considerations in the application of the Ottawa Statement for CRTs in health, social, and behavioral research using a series of examples.

General Ethical Principles

Four fundamental ethical principles govern all research involving human participants: respect for persons, beneficence, justice, and respect for communities (World Medical Association, 2008; CIOMS, 2002). These principles are grounded in moral theories, the research ethics literature, and convention. Respect for persons implies the need to take seriously the autonomous choices of prospective research participants and to protect those who are incapable of making autonomous choices. The principle of beneficence obliges researchers not to inflict unnecessary harm and, where possible, to promote the good for research participants. The principle of justice may be defined as the ethical obligation to distribute the benefits and burdens of research fairly. Respect for communities implies that researchers have an obligation to respect communal values, protect and empower communities, and, where applicable, abide by the decisions of legitimate communal authorities. There is considerable debate about the applicability of biomedical ethical principles to social and behavioral research (Hoeyer et al., 2005). In the context of international research, in particular, a variety of alternative principles have been proposed that include reinterpretation of the principle of justice and novel notions such as international solidarity (Benatar, 2004).

Characteristics of CRTs

A key characteristic of CRTs is that they have a hierarchical structure, which allows the units of randomization, intervention, and observation to differ within a single study. Conventional trials in psychology and medicine have the individual as the unit of randomization, intervention, and observation.

Because CRTs allocate intact clusters with multiple observations from each cluster, they often randomize a relatively small number of independent units, but the number of observations per cluster may be relatively large. Study interventions are often complex, and may include interventions targeted at one or more levels: the cluster organization, cluster-level participants (e.g., health professionals, employers, and teachers), and individual-level participants (e.g., patients, employees, or students). Data collection procedures may similarly be at the individual level and/or the cluster level, but some CRTs use routinely collected data for outcome assessment without interaction with individuals. In such studies, outcomes may be transmitted to researchers anonymously, in the form of rates or cluster-level summaries. Analyses in CRTs may be conducted at either the individual or cluster level.

Table 1 describes characteristics of a random sample of 300 CRTs in health research published between 2000 and 2008, identified using a validated electronic search strategy implemented in Medline. Further details of the search strategy and sample are presented elsewhere (Ivers et al., 2011). The units of randomization were diverse, including primary care practices, hospitals, nursing homes, residential areas, schools, classrooms, worksites, and groups such as sports teams or social clubs. Approximately one-third of trials had interventions targeted solely at the cluster level, one-third had interventions targeted solely at the individual level, and one-third had complex interventions targeted at multiple levels. The majority of trials (72%) included data collection via questionnaires administered to individual-level participants, but one-fifth included questionnaires administered to cluster-level participants. The use of routinely collected data sources for outcome assessment was common. In just over one-fifth of studies there was no recruitment of individuals to the trial.

Reporting of ethical issues in the sample was poor (Taljaard et al., 2011): approximately one-quarter of trial reports did not include a statement about research ethics review, and one-third did not report on informed consent. In a survey of the corresponding authors of these trials (Chaudhry et al., 2013; Taljaard et al., 2014a), 70% of respondents indicated that the trial included some level of informed consent for study interventions, and 88% that it included some level of consent for data collection. Just over half of respondents indicated that consent procedures applied to participants at multiple levels. The use of 'gatekeepers' was common with 83% of respondents indicating the presence of a cluster gatekeeper in some role. Gatekeepers, also called 'guardians' or 'cluster representation mechanisms' are unique to CRTs, and are individuals or bodies that are seen to represent the interests of cluster members, clusters, or institutions.

Table 1 Characteristics of a random sample of 300 published CRTs between 2000 and 2008

Country of study recruitment	
Canada or USA	130 (43.3%)
UK or Ireland	50 (16.7%)
Other developed country	75 (25.0%)
Developing country	45 (15.0%)
Unit of randomization	
Primary care practices/professionals	121 (40.3%)
Hospitals/wards	25 (8.3%)
Nursing homes/wards	16 (5.3%)
Residential areas	47 (15.7%)
Schools/classrooms	66 (22.0%)
Worksites	16 (5.3%)
Sports teams/social groups	9 (3%)
Number of clusters randomized	
Median (IQR)	21.0 (12–52)
Range	2–605
Average cluster size	
Median (IQR)	33.9 (12.5–88.5)
Range	1.7–122855
Study interventions[a]	
Aimed at participants at cluster level	143 (47.7%)
Aimed at cluster organization	106 (35.3%)
Educational intervention aimed at individual-level participants	165 (55.0%)
Therapeutic intervention aimed at individual-level participants	51 (17.0%)
Target of study interventions	
Cluster level only	99 (33.0%)
Individual level only	105 (35%)
Both cluster and individual levels	96 (32%)
Types of control interventions	
Not reported	42 (14.0%)
No active intervention	156 (52.0%)
Minimal version of active intervention	52 (17.3%)
Placebo or sham intervention	25 (8.3%)
Other active intervention	12 (4.0%)
Wait-list or delayed intervention	13 (4.3%)
Data collection procedures[a]	
Routinely collected data	140 (46.7%)
Physical examination or other intrusive method of data collection	63 (21.0%)
Questionnaires administered to individual-level participants	215 (71.7%)
Questionnaires administered to cluster-level participants	63 (21.0%)
Levels of data collection	
Individual-level only	192 (64%)
Cluster-level only	23 (8%)
Both individual and cluster level	40 (13%)
Routine data only	45 (15%)
Any recruitment of individuals into the trial?	
Yes	233 (77.7%)
No	67 (22.3%)

[a]A trial can be classified into more than one category.

Methodological Implications of CRTs

CRTs are more complex to design, analyze, interpret, and report than individually randomized trials (Campbell et al., 2012). In a CRT, observations from the same cluster are usually positively correlated; as a result, CRTs require a larger total number of individuals to yield the same power as in an individually randomized trial (Donner and Klar, 2000). They also require special methods of analysis as standard methods assume statistical independence. Results from CRTs are more difficult to interpret because they are particularly susceptible to various sources of bias. For example, CRTs are at increased risk of baseline imbalances because the number of randomization units is often limited. For that reason, it is important to use stratification, matching, or some other method of promoting

balance in the design of the trial. CRTs are more susceptible to selection bias as individual participants may need to be identified or enrolled after clusters have already been randomized (Eldridge et al., 2009; Hahn et al., 2005). This is an important concern in CRTs evaluating behavioral interventions, as it is more difficult to blind participants to the study interventions.

A review of the methodological and reporting quality of the sample of 300 published CRTs showed that methods used in CRTs are often suboptimal (Ivers et al., 2011). Because methodologically flawed studies expose individuals to experimental interventions without the potential for scientific gain, failure to adhere to these basic requirements for CRTs may lead to studies that are inherently unethical. Therefore, it is important that investigators adopt statistical methods appropriate for this design. Multiple resources are now available to help investigators plan, conduct, analyze, and report CRTs (Campbell and Walters, 2014; Donner and Klar, 2000; Murray, 1998).

Reasons for Adopting Cluster Randomization

Because of their inherent methodological challenges, the decision to employ the CRT design requires careful justification. There are usually cogent reasons to adopt a CRT: in the case of cluster-level or professional-level interventions, the reasons are obvious; that is, the trial simply cannot be done in any other way. But in the case of individual-level interventions, the trial could – in principle – have used individual randomization. In such trials, cluster randomization may nevertheless be selected for scientific reasons (e.g., to avoid contamination and to estimate population-level effects of an intervention), or for other logistical, practical, or political reasons.

The need to avoid contamination is a common concern in CRTs. Contamination occurs when individuals in the control arm are partially exposed to the intervention through interaction with individuals receiving the study intervention, thus biasing the results toward smaller effect sizes. The risk of contamination is particularly great in the case of unblinded or behavioral interventions. For example, in a school-based CRT of an intervention to promote healthy behaviors, entire schools may be randomized to minimize the likelihood of children in different intervention groups sharing information about the trial.

Even in the case of individual-level therapeutic interventions with blinding, there may be good reasons to adopt the cluster randomized design. For example, the ObaapaVitA trial (Kirkwood et al., 2010) was a double-blind, placebo-controlled trial to evaluate the effect of weekly, low-dose vitamin A supplementation on pregnancy-related and all-cause female mortality in Ghana. A total of 1086 small clusters of compounds were randomized to either vitamin A or placebo capsules. Fieldworkers visited compounds to recruit women (approximately 100 000 per arm), distribute capsules, and gather data on pregnancies, births, and deaths. Although individual randomization could in principle have been used, the use of cluster randomization considerably simplified the trial organization and fieldwork. Randomization of clusters also minimized the possibility of women receiving the wrong capsules as fieldworkers only had one type of capsule in their possession during any week. It may also have helped to prevent the risk of sharing of capsules among women (in the hope of getting some benefit should they be randomized to placebo).

Other common reasons to adopt the CRT design include the need to secure cooperation from cluster decision makers and facilitate recruitment of participants. In Progresa, a poverty alleviation program in Mexico (Parker and Teruel, 2005), a sample of 500 rural villages were randomly assigned to intervention or control arms. In the intervention arm, poor families were offered cash transfers in exchange for sending their children to school and for regular attendance at health clinics. Officials decided against randomization at the household level as they were concerned that perceived favoritism in the selection process would have created discontent and resentment between intervention and control households within the same communities.

Ethical Implications of CRTs

While the ethics of individually randomized trials is well understood, CRTs differ from individually randomized trials in important ways; this complicates the application of established research ethics guidelines. For example, in an individually randomized trial, the units of randomization, intervention, and outcome assessment are the same (e.g., the citizen, student, and patient) – in a CRT, the units of allocation, intervention, and outcome measurement may differ within any given trial. This raises questions as to who ought to be considered research participants and whose informed consent is required. In an individually randomized trial, participants are identified and approached for consent prior to study randomization – in a CRT, clusters may be randomized before individual cluster members can be identified and approached for informed consent. This raises the question whether and from whom consent for randomization is required. In some CRTs, gatekeepers or decision makers may exist within each cluster, but it is unclear whether gatekeepers may provide consent to randomization. In individually randomized trials, the study intervention is directed at the individual, but in a CRT interventions may be directed at the level of the individual, the cluster, or both. Cluster-level interventions (e.g., public educational messages) may be difficult for individuals to avoid; in such cases, meaningful refusal of study participation is impossible. While conventional randomized trials involve individuals, CRTs involve social groups as well as individuals. However, our current understanding of the moral status of social groups, and of the gatekeepers who speak on their behalf, is incomplete. Group interests may conflict with individual interests and this complicates benefit–harm assessments. Finally, some CRTs involve very large clusters, and requiring informed consent may make the study infeasible. Further in-depth discussion of the ethical issues raised by CRTs is presented elsewhere (Weijer et al., 2011).

Examples

It is convenient to distinguish among three kinds of CRTs, depending on the level of the intervention: cluster–cluster trials (interventions delivered at cluster level), professional–cluster

trials (interventions delivered to professionals in each cluster), and individual–cluster trials (interventions delivered directly to individual cluster members) (Eldridge et al., 2005). Some CRTs may involve more than one kind of intervention.

Example 1: Cluster–Cluster Trial

The COMMIT study (Community Intervention Trial for Smoking Cessation, 1995a,b) was designed to test the effectiveness of a comprehensive, community-oriented approach to influence citizens' smoking behaviors. Twenty-two communities with populations between 50 000 and 250 000 in the USA and Canada were randomly assigned to intervention or control arms. The researchers interacted with the communities via a community advisory board, consisting of key community representatives. The intervention included activities focused on public education using mass media and organized community events, promotion of policies to restrict the sale of tobacco to youth, and development of smoking cessation resources and activities. Population-based surveys, using random digit telephone dialing, were used to measure outcomes. Before randomization and at the end of the study, cross-sectional samples of approximately 2500 households per community were surveyed about their smoking behaviors. In addition, cohorts of approximately 550 heavy and 550 light-to-moderate smokers were identified in each community and followed to assess quit rates. Although the intervention significantly improved quit rates among light-to-moderate smokers, there was no significant effect on quit rates among heavy smokers or on the community prevalence of smoking.

Example 2: Professional–Cluster Trial

The Guidelines Trial (Althabe et al., 2008) was a CRT to evaluate a multifaceted behavioral intervention to improve the use of episiotomy and management of the third stage of labor, targeted at birth attendants in Latin America. Nineteen hospitals (approximately 500 birth attendants) in Argentina and Uruguay were randomized to either intervention or control arms. In the intervention arm, teams of birth attendants (physicians, residents, and midwives) were identified as opinion leaders and participated in a workshop to develop clinical guidelines. Teams returned to their respective hospitals, disseminated guidelines, trained other birth attendants, and implemented a system of reminders and feedback. Birth attendants in the control arm received no intervention. Rates of episiotomy and prophylactic use of oxytocin in the third stage of labor were collected from approximately 5500 births using a standard clinical record form. No information identifying individual women was transmitted from the hospitals. Birth attendants completed self-administered questionnaires measuring their readiness to change their behaviors. Responsible authorities from all the hospitals provided written permission, and birth attendants provided written informed consent for study participation. Rates of prophylactic oxytocin use increased significantly; rates of episiotomy use decreased significantly in intervention versus control hospitals. Approval for the study was obtained from eight institutional review boards.

Example 3: Individual–Cluster Trial

Robroek et al. (2012) evaluated a CRT to evaluate the effectiveness and cost-effectiveness of an individually tailored worksite health promotion program designed to improve employees' physical activity and nutrition. The intervention was delivered at the individual level, but worksites were chosen as the units of randomization to enhance compliance and promote adherence using the worksite as a natural social network. Worksites randomized to the intervention arm received computer-tailored physical activity and nutrition advice, a monitor function that allowed individuals to chart their progress, a personal coach who gave continuous feedback and support through monthly e-mails, and the opportunity to seek advice from a range of professionals. The primary outcomes were compliance with national recommendations on physical activity and fruit and vegetable intake, assessed by means of questionnaires and physical examination. After obtaining agreement from the employer, 74 eligible worksites were randomized; a total of 924 employees who provided written informed consent were enrolled in the study. No statistically significant effects due to the intervention were observed. The local REC approved the study.

The Ottawa Statement

The Ottawa statement sets out 15 recommendations for the ethical design and conduct of CRTs, covering the justification of cluster randomization, the need for REC review, the identification of research participants, obtaining informed consent, the role of gatekeepers in protecting group interests, the assessment of benefits and harms, and the protection of vulnerable participants. The specific recommendations are summarized in **Table 2**. Here we interpret recommendations in the Ottawa Statement with respect to CRTs in health, social, and behavioral research using three examples.

Justification for the CRT Design

Recommendation 1 of the Ottawa Statement requires that the choice of cluster randomization be carefully justified. The design should not be adopted in the mistaken belief that the need for informed consent can be avoided. In example 1 (COMMIT) the choice was obvious as it involved a community-wide smoking cessation campaign; likewise in example 2, it would have been impossible for birth attendants to avoid letting the training influence treatment of all women under their care. In example 3, the intervention was an individually tailored health promotion intervention, and employees could, in principle, have been randomized individually. In this trial, entire worksites were randomized to avoid contamination, as well as to enhance compliance with the intervention.

Need for Research Ethics Review

National and international research ethics guidelines stipulate that all human research must be submitted to and

Table 2 Ottawa statement: summary of recommendations

	Ethical issue	*Recommendation*
1	Justifying the cluster randomized design	Researchers should provide a clear rationale for the use of the cluster randomized design and adopt statistical methods appropriate for this design
2	Research ethics committee review	Researchers must submit a CRT involving human research participants for approval by a research ethics committee before commencing
3	Identifying research participants	Researchers should clearly identify the research participants in CRTs. A research participant can be identified as an individual whose interests may be affected as a result of study interventions or data collection procedures – that is, an individual who is the intended recipient of an experimental (or control) intervention; or who is the direct target of an experimental (or control) manipulation of his or her environment; or with whom an investigator interacts for the purpose of collecting data about that individual; or about whom an investigator obtains identifiable private information for the purpose of collecting data about that individual. Unless one or more of these criteria is met, an individual is not a research participant
4	Obtaining informed consent	Researchers must obtain informed consent from human research participants in a CRT, unless a waiver of consent is granted by a REC under specific circumstances
5		When participants' informed consent is required, but recruitment of participants is not possible before randomization of clusters, researchers must seek participants' consent for trial enrollment as soon as possible after cluster randomization – that is, as soon as the potential participant has been identified, but before the participant has undergone any study interventions or data collection procedures
6		A research ethics committee may approve a waiver or alteration of consent requirements when the research is not feasible without a waiver or alteration of consent, and the study interventions and data collection procedures pose no more than minimal risk
7		Researchers must obtain informed consent from professionals or other service providers who are research participants unless conditions for a waiver or alteration of consent are met
8	Gatekeepers	Gatekeepers should not provide proxy consent on behalf of individuals in their cluster
9		When a CRT may substantially affect cluster or organizational interests, and a gatekeeper possesses the legitimate authority to make decisions on the cluster or organization's behalf, the researcher should obtain the gatekeeper's permission to enroll the cluster or organization in the trial. Such permission does not replace the need for the informed consent of research participants
10		When cluster randomized trial interventions may substantially affect cluster interests, researchers should seek to protect cluster interests through cluster consultation to inform study design, conduct, and reporting. Where relevant, gatekeepers can often facilitate such a consultation
11	Assessing benefits and harms	The researcher must ensure that the study intervention is adequately justified. The benefits and harms of the study intervention must be consistent with competent practice in the field of study relevant to the cluster randomized trial
12		Researchers must adequately justify the choice of the control condition. When the control arm is usual practice or no treatment, individuals in the control arm must not be deprived of effective care or programs to which they would have access, were there no trial
13		Researchers must ensure that data collection procedures are adequately justified. The risks of data collection procedures must be minimized consistent with sound design and stand in reasonable relation to the knowledge to be gained
14	Protecting vulnerable participants	Clusters may contain vulnerable participants. In these circumstances, researchers and RECs must consider whether additional protections are needed
15		When individual informed consent is required, and there are individuals who may be less able to choose participation freely because of their position in a cluster or organizational hierarchy, RECs should pay special attention to recruitment, privacy, and consent procedures for those participants

Source: Weijer, C., Grimshaw, J.M., Eccles, M.P., McRae, A.D., White, A., Brehaut, J.C., et al., 2012. The Ottawa statement on the ethical design and conduct of cluster randomized trials. PloS Medicine 9 (11), e1001346. http://dx.doi.org/10.1371/journal.pmed.1001346.

approved by a REC (World Medical Association, 2008; CIOMS, 2002). Research may be defined as a systematic investigation designed to produce generalizable knowledge. CRTs generally meet the definition of research and must be reviewed by an REC (recommendation 2). All of the three examples meet the definition of research and hence should have been reviewed by RECs. RECs ought to take a proportional approach to the review of study protocols; thus, protocols not involving vulnerable participants and posing only low risk to research participants may be eligible to undergo expedited or delegated review. While there is a common perception that socio-behavioral research poses only low risk to research participants, examples of unintended harm to participants as a result of seemingly innocuous research exist (Phillips, 1994).

Identification of Research Participants

The identification of human research participants is an ethical requirement before consent procedures and harm–benefit issues can even be considered. Failing to accurately identify research participants in CRTs may have differing

consequences: on the one hand, being overly inclusive may lead to unnecessary regulatory burdens that can hamper important research; on the other hand, failing to identify someone as a research participant may lead to inadequate protections of their interests. A defining feature of a 'research participant' is someone whose interests are affected by study interventions or data collection procedures (McRae et al., 2011a). Based on this definition, the Ottawa Statement provides four criteria for identifying research participants in a CRT (recommendation 3). Individuals classified as research participants are entitled to regulatory protections, including assessment by an REC of study benefits and harms, informed consent provisions, and subject selection procedures.

In example 1 (COMMIT), the entire community was being intervened upon through the cluster-level intervention, and thus all residents were research participants. Although residents in control communities were not targeted by any study interventions, their interests may be affected by being denied access to a potentially beneficial intervention, and thus, they were also research participants. Community residents participating in the surveys were research participants as they interacted with investigators for the purpose of data collection. Birth attendants in example 2 were intervened upon through training sessions and reminders and completed questionnaires; thus, birth attendants were research participants. However, women giving birth were not research participants: although the women may have been indirectly affected by the interventions directed at the birth attendants, the birth attendants continued to have an obligation to act in their patients' best interests and the fidelity of the health provider–patient relationship was preserved. Since women were not directly intervened upon by researchers and did not provide researchers with identifiable private information for research purposes, the women were not research participants (McRae et al., 2011a). Employees in example 3 were research participants as they were directly intervened upon and interacted with researchers for the purpose of data collection.

Informed Consent Requirements

The ethical principle of respect for persons generally requires that researchers seek the informed consent of prospective research participants. The consent process allows potential participants to adopt the ends of the study as their own instead of being treated merely as a means to an end. In CRTs, consent is required only from those cluster members who are research participants (recommendation 4). When cluster members are not research participants, their informed consent for research is not required.

National and international research ethics guidelines provide detailed disclosure requirements for consent processes, including information about the purpose of the study, study interventions and data collection procedures, the potential benefits and risks of study participation, and alternatives to participation. In individually randomized trials, participants usually consent to randomization, intervention, and data collection prior to study enrollment. Because the units of allocation, intervention, and data collection may be different in CRTs, consent for these three aspects of the trial may need to be sought separately. For example, professionals may need to provide consent for study interventions, while individuals may need to consent to data collection.

In example 2, birth attendants were research participants and their informed consent was required for both study interventions and completion of questionnaires; however, the informed consent of patients was not required as they were not research participants. In example 3, employees were research participants, and required to consent to the study interventions as well as data collection procedures.

Timing of Consent

Recommendation 5 of the Ottawa Statement requires researchers to identify participants and seek their consent before cluster allocation. However, in many CRTs, it is not possible to approach or even identify eligible participants before allocation of clusters. In such cases, researchers should seek potential participants' consent as soon as possible after the participant has been identified, before administering any study interventions or data collection procedures. Seeking informed consent as soon as possible and before any study interventions or data collection procedures satisfies the moral purpose of informed consent (McRae et al., 2011b). In these circumstances, consent to randomization is not required. However, researchers should be aware that post-randomization consent increases the risks of selection bias (Eldridge et al., 2009; Hahn et al., 2005). In example 3, it would have been both ethically and methodologically advantageous to identify and obtain employees' informed consent prior to randomization, if this were feasible. When investigators believe that practical or logistical issues mean that obtaining such consent is infeasible, they must justify this to the satisfaction of the responsible REC and obtain individual consent as soon as feasible and prior to the study interventions or data collection procedures.

Feasibility of Consent

In CRTs with cluster-level interventions (e.g., COMMIT), individual informed consent for study intervention is usually not feasible because there is no meaningful way for an individual to opt out or avoid the intervention. In such cases, researchers may apply for a waiver of consent for the study intervention, provided it presents no more than minimal risk to research participants (recommendation 6). Waivers of consent apply in some jurisdictions, and imply that the REC removes the requirement to obtain informed consent. 'Minimal risk' refers to the risks of daily life of the study population. Various study procedures are commonly regarded as presenting only minimal risk, including questionnaires and interviews covering nonsensitive topics (e.g., topics other than mental health, sexually transmissible diseases, or violent or criminal behavior), physical examination, noninvasive medical monitoring, and review of medical records (assuming adequate protections of confidentiality are in place). The researcher is responsible for adequately justifying to the REC that obtaining informed consent is infeasible and that study participation poses only minimal risk. However, a waiver of consent may not extend to all study procedures. For example, even if a waiver of consent is granted for study intervention,

researchers may nevertheless be required to seek participants' consent for data collection.

In some CRTs, seeking individual consent for data collection may be logistically impossible (e.g., due to extremely large cluster sizes), but data may nevertheless be available from secondary data sources. If informed consent to the use of individuals' identifiable information is not feasible, the researchers may apply for a waiver of individual consent on the grounds that the research could not practicably be carried out otherwise.

In some CRTs, researchers may be concerned that information disclosed during the informed consent process may lead to either selection or response bias. In such cases, they may appeal to an REC for a waiver or *alteration* of consent, which means that the REC permits changes to or removal of some of the standard elements of disclosure in the informed consent, for example, by allowing incomplete disclosure of the nature of a behavioral intervention. Alterations of consent procedures are subject to the same restrictions as waivers; that is, the risk of bias must make the study infeasible and study interventions must pose no more than minimal risk. In example 1 (COMMIT), cohort members were not explicitly notified of their status as cohort members, but were informed that they would be contacted annually. In example 3, employees were blinded as to the exact nature of the intervention in order to minimize the risks of participation or response bias. As far as possible, researchers should avoid having differential consent procedures in the intervention and control arms of the study to minimize the risks of bias (Eldridge et al., 2009; Hahn et al., 2005).

Informed Consent in Organizations

CRTs taking place in organizations or worksites may contain vulnerable cluster members whose presence is not obvious. For example, individuals in subordinate positions may be less able to freely choose whether they wish to participate in the trial. Researchers should take special care to identify and protect vulnerable participants in CRTs (recommendation 14) and pay special attention to their recruitment, privacy, and consent procedures (recommendation 15). When professionals (such as physicians, nurses, teachers, and managers) are research participants in CRTs, their informed consent may be required unless conditions for a waiver of consent obtain (recommendation 7). Recruitment of professionals in CRTs should be free of coercive influence from supervisors, administrators, or organization leaders. In such cases, consent procedures should include discussions about career-related risks (e.g., due to detection of possible negligence or incompetence). Data about professional performance should be kept confidential within the research team, except in cases of gross negligence or incompetence where statute or professional obligation mandates disclosure to a professional certifying or licensing body. This possibility should be disclosed to potential research participants in the informed consent process.

The Role of Cluster Gatekeepers

Gatekeepers are individuals or bodies who may be called upon to represent the interests of cluster members, clusters, or institutions. Examples of gatekeepers in CRTs include village elders, mayors, school principals, employers, or hospital administrators. Although gatekeepers have traditionally played an important role in CRTs due to challenges in seeking individual informed consent, such concerns may be mitigated by careful identification of research participants and application of waivers of consent (Gallo et al., 2012). Gatekeepers do not have the authority to provide proxy consent on behalf of cluster members, and CRTs should not proceed on the basis of such 'consent' (recommendation 8). However, gatekeepers do have an important role with respect to the protection of group or organizational interests affected by a CRT. As long as a gatekeeper's role within the cluster or organization endows them with the authority to make decisions on behalf of the cluster, and as long as cluster members recognize this authority, researchers may approach a gatekeeper for permission to enroll a cluster in a trial. A school principal, for example, may provide permission to researchers to access the school after considering availability of staff, resource implications of participation, and the likelihood that teachers or students would be willing to participate.

Gatekeepers may also facilitate consultation between researchers and cluster members about the goals, design, and implementation of the study, as well as dissemination of research findings. Consultation with cluster members may protect group interests by subjecting the study to examination and discussion by those whose interests may be affected. Gatekeepers may have the authority to withdraw a cluster from an ongoing CRT. As cluster withdrawals can have serious consequences for participants as well as the scientific validity of a CRT, researchers should make every reasonable effort to retain all enrolled clusters in the trial. In some trials, the intervention may be offered to clusters allocated to the control arm as a way to help secure their cooperation and prevent attrition.

In example 1 (COMMIT), the researchers recognized the need for community permission and consultation: the communities (via the community advisory boards) were closely involved in the planning and implementation of the trial. In example 2, hospital authorities legitimately provided permission to conduct the study in their facility and provided access to the anonymized data from individual births. They may also have facilitated consultation with birth attendants, doctors, and nurses about specific aspects of the trial, but this was not a substitute for the informed consent of birth attendants. In example 3, employers legitimately had a role to protect the organizational interests, and provided permission to include sites in the trial (but not to enroll individual employees in the trial).

Conclusion

CRTs are clearly distinguishable from individually randomized trials; they have unique methodological and ethical requirements. Once the decision to use cluster randomization has been adequately justified, investigators must adopt statistical methods appropriate for the CRT design. CRTs may involve multiple kinds of participants, not all of whom will meet the criteria for research participants: informed consent is not required from those who are not research participants, while waivers of consent may obtain in many other cases. Gatekeepers cannot legitimately provide consent for randomization or study procedures on behalf of cluster members and have

a limited role in protecting individual interests. They do in some cases have a legitimate role in protecting group or institutional interests.

Prior to publication of the Ottawa Statement, there were no comprehensive ethics guidelines specific to CRTs; as a result, researchers and RECs had to rely on ambiguous interpretation of standard research ethics guidelines designed with individually randomized trials in mind. This contributed to considerable uncertainty and variability in the conduct and ethics review of CRTs within and among different jurisdictions. Here we interpreted key recommendations in the Ottawa Statement with respect to CRTs in health, social, and behavioral research. There is increasing interest in the use of CRTs in education, welfare, crime prevention, and economic development (Boruch, 2005). Future research may focus on the application of the Ottawa Statement to CRTs in these areas. Finally, given the rapidly expanding nature of the field, the authors of the Ottawa Statement anticipate the need for significant revisions and additions to the guidelines over the next 5 years.

Abstract

Social networks are not homogeneous but typically grouped into subsets of strongly reconnected groups. Here we review the literature on structural cohesion and clustering in networks. We divide our review into sections based on overall measures of cohesion and approaches to finding subgroups in larger networks.

Introduction

Network cohesion and clustering are important for understanding how social networks shape communities, facilitate norm maintenance, or form the basis of categorical group identity, among many other things (Freeman, 1992; Pescosolido and Rubin, 2000; Martin, 2009). Substantively, we expect that norms and diffusion circulate more readily within cohesive networks, and that clusters of people connected to each other – peer groups or crowds – are likely to be similar. If we seek to measure cohesion and identify clusters in networks, then we must answer two related methodological questions. First, how best to operationalize cohesion on a network and second, how to identify the naturally occurring 'cohesive subgroups' that emerge in most social settings. This article reviews current work on the related problems of structural cohesion and clustering in social networks.

We understand social networks as graphs of social relations, G(V,E), where the nodes (V) of the graph are typically people and the relations (E) are some positive social connection, such as friendship, love, or communication, linking pairs of nodes (for the substantive problem of cohesion, relations should be thought of as carrying positive social meaning rather than mere contact or negative relations. See Friedkin (2004) for further reflections on the relations between individual and group cohesion). Relations can be directed and valued, although most of the discussion below will focus on binary undirected networks for simplicity. A path in the network is a (possibly directed) sequence of nodes and edges starting and ending with a node but never repeating. Two nodes are said to be reachable if there is a path from one node to the other, and the graph is connected if all pairs are reachable. Two paths are node (edge) independent if they share the same start and end nodes but overlap on no other nodes (edges). The geodesic distance is the shortest path connecting two nodes. If there is no path connecting a pair, we define the distance as infinite. A cycle is a path that starts and ends on the same node. The density of a graph is the average value of edges calculated over all pairs: $(\sum_{ij} A_{ij})/[N(N-1)]$.

Structural Cohesion

Cohesive networks should be difficult to separate. For cohesive networks, the relations should bind the collective together. In such settings, we expect that people have many ties with others and that the ties are widely distributed (rather than routing through one node). In cohesive networks, people are generally close to each other (Moody and White, 2003; Friedkin, 2004).

The archetypical structural pattern capturing these intuitive cohesion ideas is the clique (Luce and Perry, 1949; Alba, 1973): a collection of nodes with edges connecting every pair in the network. Every node in a clique of size n is connected to all $n-1$ other nodes. The complete nature of a clique leads to maximal values on other features, which have typically been used as indicators of cohesion or clustering. For example, the density of a binary graph is 1, the distance between all nodes is 1, and every pair has $n-2$ contacts in common, implying that all triads within the graph are complete. Disconnecting a clique requires deleting at least $n-1$ edges or nodes.

The complete adjacency requirement of cliques means they are substantively difficult to use in real-world data settings where some element of randomness is usually present. First, known substantive groups are rarely complete cliques, as any missing edge undermines the complete connectivity requirement. (Moreover, if a survey design for collecting network data has limited the respondent to nominating k alters, then the maximal size of clique in the network must be k.) Second, since cliques can overlap (by as many as $k-1$ nodes), attempts to use cliques as markers for cohesion frequently must aggregate overlapping clique memberships (Palla et al., 2005; Evert and Borgatti, 1998). This leads researchers to search for groups that are 'clique like,' but not complete. Understanding exactly what counts as 'clique like' has been the heart of the methodological challenge in this area, but most have focused on relaxing one of the dimensions that defines a clique, effectively capturing how 'close' to a pure clique a given graph might be.

The simplest (because it involves only summing edges) such generalization has been to use the graph's density. While intuitive (cohesive groups should be dense), density is an insufficient measure of cohesion. Consider Figure 1, which shows three networks with the same density, but differing path structures, and thus substantively different cohesion (for how density nonetheless constrains structure, see Faust, 2006) This general sort of problem, that networks have the same score on a given clique-maximal characteristic nonetheless have different structures that clearly imply varying cohesion, is at the heart of the difficulty in generalizing clique features to measure cohesion. This is true for many attempts at measuring cohesion, such as the distance between nodes in a group (N-Clique, Bron and Kerbosh, 1973), the average number of nodes each node is connected to (the k-plex or k-core, Seidman and Foster,

Figure 1 Three graphs with same density but different cohesion.

Figure 2 Graph with high edge connectivity but low node connectivity.

1978), or the proportion of transitive triples (such as the clustering coefficient (Watts and Strogatz, 1998). At the heart of the problem is the understanding that cohesion rests on levels of connectivity – on the pattern of paths as much as the volume of ties.

In response to the ambiguity of these many measures, Moody and White (2003) introduced node connectivity as a necessary measure of structural cohesion. Starting with the simple idea that cohesion must at a minimum imply connectivity, Moody and White argued for generalizing connectivity based on the difficulty of disconnecting a network. A graph can be disconnected by removing either nodes or edges. Edge connectivity is the minimum number of edges that one has to remove to disconnect the graph, while node connectivity is the minimum number of vertices one has to remove to disconnect the graph. While these might seem similar, it turns out that one can easily have high edge connectivity even if node connectivity is low, while the opposite is not true: high node connectivity implies high edge connectivity. As an illustration, consider Figure 2. Here the graph is four-edge connected but one-node connected, meaning that graph resilience is dependent on the center star-like cut-node. Since social cohesion turns on the supraindividual character of the setting (Simmel, 1950), node connectivity better characterizes the intuitive notion that a cohesive group is held together but not dominated by a single node, and thus Moody and White take biconnectivity (two-node-separable graphs) as the fundamental starting point for structural cohesion.

Node connectivity implies other features that similarly map well to our understanding of social cohesion. First, a k-connected component implies that every pair of nodes is connected by at least k-node-independent paths and implies $(k-1)$ node-independent cycles among all pairs in the graph. This means that k-components (for $k > 1$) contain multiple paths between pairs that never cross the same set of nodes. For social networks, the existence of multiple paths implies many alternative routes through the network that could generate high levels of information diffusion (see Centola and Macy, 2007

Figure 3 Nested *k*-components of a network.

for related ideas with respect to diffusion) and promote the conditions necessary for enforceable trust, a key element for norm formation (Mark, 1998).

Node connectivity implies a hierarchical ordering of the groups in the network, since higher valued *k*-components are nested within lower valued *k*-components. For example, all nodes in Figure 3 are members of a (1-)component. Nested within this are two bicomponents (sets {1–8}, {9–12}) and nested within the largest bicomponent is a three-component ({3–8}). The full enumeration of the nested node components provides a cohesive blocking of the network and is a complete summary of the structural cohesion of the graph. The depth of involvement within this hierarchical structure is a natural operationalization of network embeddedness (Grannovetter, 1985; Uzzi, 1999), and thus the highest value *k*-component within which any given node is nested is recommended. Moments, such as the mean, of the distribution of pairwise joint maximal cohesion provide simple global summaries, although the minimum is the most theoretically consistent measure of overall network cohesion (the network is as strong as the weakest link).

Relative Density Measures

Moving from the network as a whole to subgroups within a network, many recognize that ties within a group typically come at the expense of ties between groups (Freeman, 1992). Thus, we expect that group (we follow the sociological convention and refer to these collections of nodes as 'groups,' the other common terms used in statistical physics or biology include 'communities' or 'modules', respectively) members interact with each other more often than with others, and measures based on this balance between intra- and intergroup ties are common. Theoretically, we should distinguish the relations within the group (what is best thought of as cohesion per se) from the structural distinctiveness of the group – the level of boundary crossing represented by between-group ties. (To give an intuitive sense of the difference, imagine two systems with multiple clusters but no ties between the clusters. In that case the relative density measures would be the same for any internal cluster density above zero.) Node cohesion implies a particular path structure within groups (*k*-node-independent paths between all pairs) and maximal contact between groups (cannot be more than $k-1$). Building on this basic balance of within versus between-group ties, a natural measure for how grouped a network is would be a relative score for the ties within compared to the ties between. One can easily summarize the group-level tie counts with a mixing matrix, where each row and column represents a group, and cell values are the count of relations within/between groups. Relative density measures are some function of the values on the diagonal compared to the values off the diagonal. An example is given in Figure 4, with the groups indicated by the shaded ellipses under the network. The mixing matrix cells provide tie counts (top number in each cell) and expected values under independence (bottom).

There had been some debate over the optimal function to weight within and between-group ties. Freeman (1978) introduced the segregation index, as $(E-O)/E$, where E is the number of expected cross-group ties and O is the number of observed cross-group ties. The logic of this index is that segregation implies difference from random mixing: If ties were distributed randomly with respect to the group labels, we would find as many observed as expected, and the score would be zero (completely nonsegregated). If, on the other hand, groups were strongly bounded we would observe very few cross-group ties, and the score would approach one. Thus the measure interpolates between negative values (more cross-group ties than within-group ties), random mixing (0), and strongly bounded groups (1.0). Similar scores simply take the ratio of diagonal cells to off-diagonal or the odds ratio of a within-group tie (overall or group specific, see Frank, 1995). Each of these scores can be calculated for the network as a whole or for specific groups.

Figure 4 Example of subgroups in a network and mixing table used for relative density measures.

Of late, the most common relative density measure is the modularity index (Newman and Girvan, 2004). The modularity index is calculated as

$$Q = \sum_{ij} \frac{1}{2m}\left(A_{ij} - \gamma\frac{k_i k_j}{2m}\right)\delta(C_i C_j)$$

where m is the number of edges, k is the degree, A is the adjacency matrix, δ is an indicator for whether node i and j are in the same subgroup or not, and γ is a 'resolution parameter' that identifies the scale at which clustering is observed (Fortunato and Barthélemy, 2007; Reichardt and Bornholdt, 2006). Substantively, $[k_i k_j/2m]$ represents the null model – the expected likelihood of contact between two nodes – here simply dependent on the degrees of the pair, so $\left(\mathbf{A}_{ij} - \left[\gamma\frac{k_i k_j}{2m}\right]\right)$ is the connectivity above random expectation, normalized by the total volume of ties in the network. This normalization is key, as it ensures that the index takes a maximum value if all ties fall within separate groups. This is the same logic as Freeman's segregation index, but because Q takes a value of 0 if there is only one group, the function must have a maximum value for multiple group partitions, which makes the quantity a very useful guide for identifying unknown communities in networks (see Porter et al., 2009 for review).

Three features of the modularity score are important to note. First, since the function can be searched for a maximum value, it had been seen as a solution to the problem of identifying the number of cohesive groups in a network. Identifying the number of naturally occurring clusters in a dataset is a long-standing problem, and for networks, most prior work required the user to specify the number of groups, or relied on principled but known-to-be arbitrary stopping criteria (Moody, 2001; Frank, 1995). Since modularity captures how grouped a network is and has a clear maximum, people had assumed that maximizing modularity automatically revealed the number of groups in the data. Unfortunately, the discovery of the resolution parameter issue (Fortunato and Barthélemy, 2007) has undone this sense of natural maximization, since changing the resolution parameter will change the number of groups that maximize Q for any given network, reintroducing an arbitrary parameter that controls the number of clusters in the group. (This is a common problem, not unique to finding groups in networks. Any stopping/selection criteria for creating distinctions in a continuum would be similar. For example, the notion that principle components extracted from a factor analysis are retained when the eigenvalue is greater than 1.0 is similarly arbitrary (Kim, 1978). The advantage of principled-but-arbitrary selection rules is that they provide a basis for consistency across studies, rather than leaving it entirely at the discretion of investigators.) Since a resolution parameter of one (i.e., ignoring the parameter) is arbitrary, the notion that the score determines the 'natural' number of found groups is not likely true.

Second, having a high modularly score only ensures that the groups as observed are distinct, not that they are internally cohesive. The modularity score will always increase if disconnected groups are assigned to distinct communities, since the score rests on the number of intragroup ties. This means that any assignment to groups that truly maximizes the modularity (see point three below) should identify internally connected groups. Beyond this simple connectivity requirement, however, the score is based merely on volume and does not ensure any formal limit on the group's internal structure.

Third, while the modularity score can be maximized, it is not necessary that the maximum modularity value correspond to a unique assignment of nodes to groups. That is, there may be many partitions on a network that all maximize modularity, but imply different substantive assignments (Bagrow and Bollt, 2005; Clauset, 2005; Good, et al., 2010). While such assignments may overlap significantly, lack of a one-to-one correspondence between maximum modularity

and group assignment has further lessened the extent to which one can depend on modularity in defining cohesive groups.

Cohesive Group Detection

While modularity is a general index for the relative volume of ties within and between specified groups, an obvious related question turns on how one identifies cohesive subgroups in a network. The field of approaches for identifying cohesive groups – called 'community detection' within the computer science and statistical physics literature – is growing rapidly. For a full review see Porter et al. (2009) or Schaeffer (2007). Here, we review the history of subgroup search procedures and outline a few of the more popular approaches. We divide the field by a basic distinction between deterministic, often graph-theoretic based, approaches and heuristic approaches that often include some level of randomization.

Deterministic Group Finding Approaches

The simplest approaches are the direct extensions of clique models discussed above. A common approach is to identify k-cores – maximal subgraphs where all nodes are connected to at least k other nodes in the set (Siedman, 1983). While every k-node-connected group is a k-core, not all k-cores are k-node connected (Moody and White, 2003; White and Harary, 2001) as such, k-cores are computationally efficient, but ambiguous. In practice, this efficiency can be useful when trying to find k-connected groups in large networks (Powell et al., 2005).

An obvious deterministic group-finding approach is to start with cliques, but real-world networks tend to have many small overlapping cliques that do not obviously represent groups. One approach is to count the number of shared cliques between nodes and treat this as a new higher order valued matrix, which can then be clustered using standard cluster or factor analysis tools (Everett and Borgatti, 1998). A nice generalization of this approach can be found with the clique percolation method (CPM) (Palla et al., 2005). CPM is a deterministic group-finding algorithm, which allows groups to overlap in a very limited way. The CPM starts with cliques of size k (k-cliques) and defines two k-cliques as adjacent if they overlap by $k-1$ nodes. A community is then the maximal union of k-cliques that can be reached through adjacent k-cliques. The communities so identified can overlap, but by no more than $k-2$ nodes (Derenyi et al., 2005), and becomes difficult to use in large networks with high values of k.

A second deterministic approach focuses on cutting the graph in careful ways. Early work used the min-cut, max-flow features to break the network into edge-connected sets (see, for example, Borgatti et al., 1990). The most popular recent work in this area divides the network removing key edges until the graph is no longer connected (Girvan and Newman, 2002). The trick to this method is to calculate 'edge-betweenness' as the number of times the shortest path between any pair of nodes passes through a given edge. One then deletes the edge with the highest score, recomputes the edge-betweenness score for the remaining edges, and repeats until the graph is disconnected. This is the first cut of the graph. One then repeats the method on the resulting components. The algorithm is computationally intensive, but seems to perform quite well (note the procedure is theoretically deterministic, but ties in the edge-betweenness level will require a tie-breaking rule, which is often random).

A third sort of deterministic clustering rests on functions of the underlying eigenstructure of the network. This has emerged repeatedly, variously seen as applications of principal component analysis (Cairns and Cairns, 1994), peer influence models (Moody, 2001), or spectral clustering (Newman, 2006). Early social network researchers used principal components or factor analysis to identify groups from interaction (e.g., Wright and Evitts, 1961) or nomination matrices (e.g., Bock and Husain, 1952; MacRae, 1960; Bagwell et al., 2000). The approaches share the premise that groups can be conceptualized as individuals whose friendships are similar (i.e., correlated). A common practice is to run factor analysis tools on the observed network, then retain all factors with eigenvalues greater than 1.0 and factor loadings above a predetermined threshold (see Gest et al., 2007 for comparison).

This approach has clear links to the block-modeling traditions rooted in CONCOR (The CONvergence of iterated CORrelations, White et al., 1976), where actors are classified as similar if they have similar nomination patterns to/from others in the network. At their core, these models share a use of eigenvalues (or close approximations of eigenvalues) as the key information source to identify the partition. Such models work because the eigenstructure captures an underlying random-walk process that maps well onto diffusion ideas, which are captured by cycles and redundancy in the network. As such, these models are likely well suited to link groups to behavior, as the underlying model is concordant between the two features of groups.

Search/Optimization Approaches

Another general approach to finding groups in networks involves searching over possible partitions to optimize some function that identifies the best assignment of nodes to cohesive groups. In theory, one could imagine assigning nodes to groups exhaustively: trying all possible assignments until the best possible solution is found. Since such exhaustive search is computationally prohibitive for any real-world sized networks, we instead use heuristic approaches that aim to efficiently approximate an ideal assignment of nodes to groups. In general, these approaches must balance between computation costs, accuracy, and arbitrariness. For example, a simple way to reduce computation cost is to have users specify the number of groups, but that is often an arbitrary choice. One can also reduce computation by using graph approximations, which sacrifices accuracy. Since most of the metrics used to optimize heuristics are based on some version of a relative density score (modularity, Freeman's segregation index, odds ratio), all the problems associated with those scores carry over to heuristics designed to optimize them.

Direct optimization routines seek to sort nodes into cohesive groups in a manner that maximizes some clustering objective function. The Newman (2004) greedy method is one such agglomerative technique that consecutively combines nodes to form large groups. Starting with each node in its own group, the routine joins groups together in pairs, choosing the

pairing that maximizes the increase in modularity. The Louvain method, implemented by Blondel et al. (2008), is an extension of this idea, locally optimizing modularity then replacing communities with 'supernodes' and links between communities as weighted ties, yielding a smaller network. This iterates until modularity is maximized, leading to a hierarchical nesting of nodes.

In a similar vein on a different metric, Ken Frank's Klique-Finder (Frank, 1995) optimizes the odds of an in-group tie directly. The objective function can then be represented as a logistic regression model of the form

$$\log\left(\frac{p(A_{ij} = 1)}{p(A_{ij} = 0)}\right) = \theta_0 + \theta_1 \text{ samegroup}_{ij}$$

So the task is to identify the group assignment labels in a way that maximizes the mixing parameter θ_1. The procedure for making this assignment involves identifying a seed triad, adding nodes to the group until no improvement is made, then starting with a new seed, and repeating this assignment process until all nodes are in initial groups. A similar approach is used with latent space group models (Krivitsky et al., 2009).

In many of these approaches, initial decisions and ties in clustering values can create assignments that are locally optimal but not globally optimal. A higher order pass through the data can then be used to move members between identified groups, merge groups, or split groups. A formal model for this sort of higher order mixing was proposed by Kernighan and Lin (1970) (see also Newman, 2006), but similar ideas are implemented in Frank's Kliquefinder and Moody's (2001) algorithm, among others.

A new development in group-finding tools extends the model to dynamic networks (Mucha et al., 2010). Here the task is to identify clusters based on the evolution of the network. The key insight builds on the random walk/diffusion notions embedded in eigenmodels discussed above, but applies the process to a graph containing two sorts of links: those connecting nodes to each other within time slices and those connected nodes to themselves across time slices. The result is a 'multislice' network, and modularity maximization tools can then be run over the entire compiled network.

Summary and Conclusion

Cohesion is a seeming simple idea that becomes more complicated once we attempt to operationalize it in real data. The problem is fundamental to the phenomena: Real-world data are ambiguous and messy, but analysts prefer simple (exhaustive and mutually exclusive) groups with strict graph-theoretic definitions or searches without arbitrary parameter choices. While we have made progress in operationalizing structural cohesion overall (Moody and White, 2003), the algorithm is complex (i.e., slow in large networks), and the resulting cohesive blocking does not lend itself to a simple scalar representation. Work on subgroup detection methods is developing rapidly, so it is too soon to conclude that line of reasoning. However, the fundamental challenge here is that we appear unlikely to identify a single detection method that has no arbitrary parameters and can identify real underlying groups with certainty. Instead, there is always the risk of multiple equivalent partitions and only locally optimal searches, with even these distinctions dependent to some degree on user-specified parameters. This implies that any search for groups in networks needs to be empirically informed by theory and knowledge of the setting, to help provide external validation for claimed group assignments. This is, then, a rich and open area for future research.

Co-constructivism in Educational Theory and Practice

Abstract

Though it is widely accepted that learning is a constructive process, it is also a social activity. People should not be considered as solo learners, but as interacting with each other and as being shaped through collaboration and discourse. The basis of personal development, therefore, is not isolated construction of knowledge, but rather its coconstruction in a socially shared, cultural space. While classrooms, consequently, should develop from aggregations of solo learners to communities engaged in dialogues and collaborative learning, the teachers' role extends from direct instruction to adaptive guidance and scaffolding of students.

Ever since Piaget's dynamically Kantian epistemology (Piaget, 1925, 1975), it has been widely accepted as a pervasive assumption that learning is a constructive process. In contrast to the epistemological assumption of empiricism that what we know is a direct reflection of ontological reality, learning is considered as an active construction of knowledge. Learners, as they strive to make sense of their world, do not passively receive stimulus information matching independent physical structures, but genuinely interpret their experience by (re)organizing their mental structures in successive cycles of assimilation and accommodation, while *interacting* with the physical and symbolic environment. According to Piaget and most of his successors in cognitive, developmental, and educational psychology, this process of adaptive and viable reality construction is enabled and constrained both by biologically grounded structures (the strength and scope of which, however, are not yet well known) and by the already existing prior knowledge (concepts, operative schemas, and structures) of the individual.

Even though the constructivist assumption makes some traditional problems in both psychology and education easier to solve, it also raises some new ones. An important problem is how we can think of achieving intersubjectivity while individually constructing meaning and knowledge. How can individuals who personally build their knowledge independently of each other come to the same or similar cognitive structures and common world views? How can we *share the* knowledge of our culture if people are conceived of as being solo learners, and socially isolated Robinson Crusoe figures?

The answer to this seminal question, challenging traditional (Western) epistemological constructivism which is foremost based on the concept of individual learning and learners, stems from symbolic interactionism (Mead, 1934) and from the explanatory framework of sociocultural theory (Vygotsky, 1962). It claims that the minds of human beings are fundamentally social products and that learning is a *social activity*. Learning and enculturation are not bounded by the individual brain or mind but are intrinsically social endeavors, embedded in a society and reflecting its knowledge, perspectives, and beliefs. People construct their knowledge, not only from direct interaction with the physical world and personal experience, but also from interacting with each other, including being told by others and by being shaped through social experience, collaboration, and discourse. The basis of personal development and enculturation, thus, is not the socially isolated construction of knowledge, but its coconstruction in a social and cultural space. Or, as Bruner puts it: "Most learning in most settings is a communal activity, a sharing of the culture. It is not just that the child must make his knowledge his own, but that he must make it his own in a community of those who share his sense of belonging to a culture" (Bruner, 1986: p. 86). Knowledge, from this perspective, is no longer seen as solely residing as a kind of possession in the head of each individual, but as being created and shared by communities, and distributed across individuals whose coordinated joint commitment to shared goals, mutual interactions, and continual (re)negotiation of meaning determine decisions, the formation of concepts, and the solution of problems.

Concept and Process of Coconstruction

No precise and widely accepted definition of the concept and process of coconstruction can be found in psychological or educational literature. What has been provided is very diverse and depends on the theoretical context in which it is embedded. Differences can be found with regard to at least three aspects:

1. the social type of discourse eligible to be called coconstructive: mother–child dialogue, peer interaction, teacher–student interaction, problem solving in pairs, learning in teams or learning communities, computer-supported collaborative work;
2. the psychopedagogical processes involved in productive coconstructive activity: productive dialogue such as exploratory talk and collective argumentation, collaborative negotiation after sociocognitive conflict or as a process of reciprocal sense-making, joint construction of a shared understanding, elaboration on mutual knowledge and ideas, giving and receiving help, instructional dialogue with a teacher or expert, tutoring and scaffolding;
3. the expected outcomes of collaboration: taken-as-shared individual vs. socially shared cognitions; convergence and intersubjectivity; academic task fulfillment, student motivation, and conceptual development; effects on skills in listening, discussion, disputation, and argumentation.

Common to most theoretical contexts of coconstructivism is the implication of some kind of social interaction, collaborative activity and, through joint patterns of awareness, of seeking

some sort of convergence, synthesis, intersubjectivity, or shared understanding, with language as the central tool and mediator for the negotiation of meaning. Theorists, moreover, largely converge in the adopted methodology of microgenetic analysis that has been used to examine the inherently fragile processes of coconstruction.

Piagetian Perspectives: The Role of Sociocognitive Conflict

In a (Neo-)Piagetian framework, genuine dialogue becomes possible and facilitates the individual cognitive construction of operational structures when children are able to take other persons' points of view into consideration (decentration) and when they are able to resolve socio-cognitive conflict. The early Piaget (2000) in particular regarded social interaction, – specifically, peer interaction – as a significant factor in individual cognitive development: "Criticism is born of discussion and discussion is only possible amongst equals" (2000: p. 409). According to later experimental studies carried out by coworkers of Piaget (e.g., Doise and Mugny, 1984; Perret-Clermont et al., 1991), social factors, such as the need to deal with conflicting perspectives in the context of pair or small group problem solving, can have a productive impact on cognitive behavior. In a Piagetian conservation task, for example, pupils more easily progressed to a subsequent level of development after having been confronted with contradictory judgments put forth by an adult or another child.

Vygotskian Perspectives of Coconstruction

In Vygotsky's cultural–historical and sociocultural view of the development of the 'higher mental functions' – viz., thinking, reasoning, and understanding – as a process of meaningful appropriation of culture, the interactive foundation of the cognitive is at the core of the developmental process. In contrast to Piaget's view, however, "the constructivist principle of the higher mental functions lies outside the individual – in psychological tools (such as 'language') and interpersonal relations" (Kozulin, 1998: p. 15). According to Vygotsky's claim that interpersonal interactions on a social plane serve as prototypes for intrapersonal processes, i.e., for functions to be internalized, coconstruction can be seen as (asymmetrical) adult–child interaction, or interaction between a child and a more advanced and capable peer or member of the society, in the 'zone of proximal development.' "What a child can do today in cooperation, tomorrow he will be able to do on his own" (Vygotsky, 1962: p. 87). The quality and development of higher order thinking is prepared by the coconstructive patterns and distinctive properties of social interaction encompassing guidance and contributions from experts or peers. Meaningful new learning emerges by embedding mental functions (like logical argumentation, proof, reflection, or problem solving) into specific forms of goal-directed interaction and dialogue, where more knowledgeable individuals adaptively tailor a task and provide cultural tools and resources in such a way that a child can successfully coperform it. The acquisition of a new concept or mental function becomes progressively more skillful as the child – in a process of apprenticeship and appropriation – learns to respond in gradually more sophisticated and personally more meaningful ways to the coconstructive, sense-mediating context of adult regulations, and eventually takes over responsibility for his or her own learning.

Perspective of Situated and Socially Shared Cognition

Situated learning theory views human cognition as being embedded in and inseparable from specific sociocultural contexts and its resources for sense-making. The goal of learning is to enter a community of practice and its culture, i.e., to learn, like an apprentice, to use cultural tools, artefacts, technologies, and rituals as practitioners and skilled members of society use them (Brown et al., 1989; Greeno et al., 1998; Rogoff, 1990; Lave and Wenger, 1991). As a process, learning takes place through the interaction and transaction between people and their environments. Coconstruction, from a situated cognition perspective, can be seen as involving two or more individuals who collaboratively construct a shared understanding, or a solution to a problem, which neither partner entirely and necessarily possesses beforehand (Chi, 1996). In a widely quoted definition proposed by Roschelle and Teasley (1995), "[c]ollaboration is a coordinated, synchronous activity that is the result of a continued attempt to construct and maintain a shared conception of a problem" (p. 70).

At the heart of this concept of coconstruction lie two coexisting activities: solving the problem collaboratively, and constructing and maintaining a *joint problem space*. Both activities require constant negotiations and recreations of meaning, i.e., trying to find out what can reasonably be said about the task in hand, and occur in structured forms of conversation and discourse, utilizing language and physical actions as their most important mediators and resources. With the use of symbolic tools, it becomes possible for the conversants to express and objectify meanings, to compare and change them deliberately, to exchange and renegotiate them with others, to build on, defend, or challenge their partner's contributions, and to reflect on the organization of judgments and arguments (see van Oers, 1996; Chi, 2009). However, as observational studies show, coconstructive learning and dialogue are hardly homogeneous but inherently fragile processes in the service of convergence and mutual intelligibility. The achievement of a shared conceptual structure cannot be reliably predicted, nor does the iterative construction of a joint problem space through cycles of displaying, confirming and repairing occur by simply putting two students together. As Roschelle and Teasley (1995: p. 94) remark:

> [s]tudents' engagement with the activity sometimes diverged and later converged. Shared understanding was sometimes unproblematic and but oftentimes troublesome. The introduction of successful ideas was sometimes asymmetric, although it succeeded only through coordinated action. These results point to the conclusion that collaboration does not just happen because individuals are co-present: individuals must make a conscious, continued effort to coordinate their language and activity with respect to shared knowledge.

Context of Linguistic Discourse Analysis

From the perspective of communication and conversation analysis, coconstructive learning requires individuals to

collaboratively establish, exhibit, maintain, and update some degree of mutual understanding. Its accountability is granted "through a plurality of displays, claiming and demonstrating understanding thanks to the mobilization of linguistic and embodied resources at specific sequential positions" (Mondada, 2011: p. 550). One of the processes by which this is accomplished between individuals is called *grounding* (Clark and Brennan, 1991). Grounding as a basic form of collaboration means the moment-by-moment coordination and synchronization of the content-specific as well as the procedural aspects and steps of coconstructive activity. There is no need, however, to fully ground every aspect of an utterance in communication. Clark and Brennan (1991: p. 148) frame a pragmatic criterion for establishing common ground: The conversants "mutually believe that they have understood what [they] meant well enough for current purposes." Thus, the techniques that are used for grounding are shaped by the goal and the medium of communication. That is, the criterion of grounding and the techniques exploited for its maintenance dramatically change according to the purpose of communication (e.g., planning a party, swapping gossip, or gaining deep understanding) and the constraints of its medium (copresence, audibility, simultaneity, and visibility in face-to-face communication; sequentiality and reviewability in written communication, e-mail, or computer-supported collaborative work).

Pedagogical Concepts of Coconstruction and Its Facilitation

An important aspect of concern for the social nature of learning – and for a pivotal way in which it is supported by culture – is instructional dialogue or conversation. This term refers to a discursive activity in classrooms that permits the coconstruction of meaning between teachers and students, tutors and tutees, the more and the less experienced, and between students. Probably, the most important feature of a culture of coconstruction in the classroom is dialogue as opposed to, e.g., solo learning and teacher monologues. Emphasis on joint learning and instructional conversation among peers, and between teachers and students, is associated with the internal mediating processes that are essential for an understanding of how coconstruction through discourse operates and influences outcomes. The pedagogical cultivation of processes such as negotiation of meaning, reciprocal sense-making, revising one's cognitions in situations of sociocognitive conflict, precise verbalization of reasoning and knowledge, listening to others' lines of argumentation, tuning one's own information to that of a partner, lending and receiving help, or modeling cognitive and metacognitive activities to be internalized by the participating individuals should, thus, be placed at the core of instructional design.

Teacher–Student Talk: Tutoring and Scaffolding

Tutoring is commonly defined as a situation in which a more knowledgeable and skilled person (in the classroom typically the teacher) provides one-to-one support to a student. Consistent with Vygotsky's theory of the constructive role played by adults in children's knowledge acquisition, the teacher's goal of assistance can be seen as trying to get the students to share his or her understanding and knowledge. Because of the asymmetrical distribution of knowledge between teachers and students, understanding might be expected to be less jointly constructed in tutorial dialogues than it is observed to be in peer dialogues. Actions that tutors or teachers can take in order to elicit responses, including some coconstructive behavior from a tutee, are described in literature on tutoring (e.g., Chi et al., 2001; Graesser et al., 2012) and cognitive apprenticeship (Collins et al., 1989). They can be subsumed under two broad categories: (1) modeling, scaffolding, and fading as content-specific ways of providing hints, strategies, and situational forms of coaching and guidance that are tailored to the needs of individual students; and (2) prompting as a more content-neutral invitation by the tutor to elicit elaborations, reflections, and self-explanations from students (Chi et al., 2001). The metaphor of *scaffolding* in particular serves as a description of a productive way of supporting student thinking and problem solving. Specifically put, the teacher helps the students make sense of a difficult task in a highly responsive way that allows as much active student participation as possible. Moreover, as Kleine Staarman and Mercer (2010) notice, "the notion of scaffolding is not merely providing a learner with help to accomplish the task, but actively and temporarily providing a learner with just the right amount of support that is geared towards bringing him or her closer to a state of individual competency" (Kleine Staarman and Mercer, 2010: p. 79).

Teacher–Student Talk: Instructional Conversations and Dialogic Teaching

A rich body of research conducted in connection with pedagogical concepts of coconstruction and its facilitation studied instructional conversation during whole-class teaching. Numerous analyses of classroom talk have shown that in most cases it is characterized by a highly asymmetric distribution of utterances in favor of the teacher, which leaves students with only few opportunities to play an actively participating and responsible role in the process of knowledge construction. Classroom talk often follows the typical pattern of IRE or IRF sequences (Mehan, 1979; Sinclair and Coulthard, 1975). Such an IRE sequence starts with a teacher question (Initiation), followed by the response of the student and the evaluation or feedback of the teacher. Usually, the majority of teachers' questions requires only brief, 'correct' answers and do not invite students to think for themselves, to generate and externalize their own ideas about the object under consideration, or to take up and examine contributions of other students. It is for this reason that there seems to be only little space left for coconstructive activities such as negotiation of meaning and reciprocal sense-making. Referring to Bakhtin's (1981) distinction between monologic and dialogic discourse, some authors deemed this structure of classroom interaction to be rather monologic than dialogic (e.g., Ford and Forman, 2006). From a sociocultural perspective on teaching and learning, however, teaching approaches which are of a more dialogic nature are required in order to foster students' deep understanding of concepts and the appropriation of cognitive and communicative strategies of the discipline being taught.

Implementing a more dialogically geared teaching approach does not mean that the teacher completely abandons his or her leading role in the discourse. Depending on the part assigned to the students and the quality of the teacher's question and feedbacks, dialogic structures are possible even within a teacher-directed setting. So, by making use of interactional moves like 'revoicing' instead of evaluating a student utterance, the teacher can position a student as "a thinker or theorizer, the holder of a noteworthy idea, or explanation" (O'Connor and Michaels, 2007: p. 281), and as an authoritative and accountable member of a knowledge building community. The distinction between monologic and dialogic discourse might therefore be too simplified, as O'Connor and Michaels notice. They distinguish two notions of dialogic discourse, namely dialogic discourse as an ideological stance and dialogic discourse considered as a linguistic discourse structure. Thus, a discourse sequence may appear rather monologic with respect to its linguistic form, but at the same time it invites students to listen to each other, to generate arguments and to negotiate a shared understanding. Mortimer and Scott (2003) pursued a similar line of argument and proposed a two-dimensional model drawing a distinction between an authoritative versus dialogic dimension on the one hand and an interactive versus noninteractive dimension on the other hand.

As research on teacher–student talk indicates, it is challenging for teachers to develop an approach to teaching which is more dialogue-oriented. Yet there are theoretically substantiated concepts and related tools available to teachers that can support such a development, for instance, 'Dialogic Teaching' (Alexander, 2008), or 'Accountable Talk' (Michaels et al., 2008). Both concepts provide teachers with a collection of concrete recommendations and strategies or tools that can support the implementation of a more dialogic culture of interaction in the classroom.

Student–Student Talk: Collaborative Learning and Patterns of Dialogues

Student–student talk during a collaborative learning activity is perhaps the most obvious example of knowledge coconstruction in the classroom. In this context, collaborative learning is defined as an activity in the course of which "participants are engaged in a coordinated, continuing attempt to solve a problem or in some other way construct common knowledge" (Mercer and Littleton, 2007; see also Section Perspective of Situated and Socially Shared Cognition). In contrast to teacher–student talk, student collaboration is usually characterized by a (more or less) symmetrical relationship between the participants as regards hierarchy and knowledge level. In pursuing different theoretical perspectives on coconstructivism (see Sections Piagetian Perspectives: The Role of Sociocognitive Conflict; Vygotskian Perspectives of Coconstruction; Perspective of Situated and Socially Shared Cognition; and Context of Linguistic Discourse Analysis), research on the processes of collaborative learning has put forward several descriptions of patterns which guide productive student–student talk in the course of which both partners substantially contribute to a topic in a relatively equal and balanced way. One of the most prominent concepts in this regard is exploratory talk (as opposed to disputational and cumulative talk; Mercer and Littleton, 2007), which is characterized as "constructive and critical negotiation of views, offering constructive criticism and building on challenges and counter-challenges" (Vass and Littleton, 2010: p. 113). Exploratory talk is likely to incorporate other characteristics reported in the literature, such as regulation of sociocognitive conflicts, argumentation, or giving and receiving elaborated explanations (see also Webb, 2009). Another concept of productive student–student talk refers to patterns of joint dialogues (Chi, 2009) "which occur when both peers make substantive contributions to the topic or concept under discussion, such as by building on each other's contribution, defending and arguing a position, challenging and criticizing each other on the same concept or point, asking and answering each other's questions" (p. 82f).

Quite a lot of both theoretical and empirical work has addressed the processes that underlie dialogues and the conditions under which collaborative interaction is most likely to occur, and a whole range of possible ways to enhance its quality has been provided. Among the input characteristics that exert a complex influence upon the quality of interaction are: the preparation of the students for collaborative learning (including training for cooperation and discourse prior to the collaborative learning event), the establishment of a culture of dialogue and of problem-based learning, group characteristics (composition, size, ability, and sex), the goal and incentive structure of the task, and the structuring of group interaction (see, for reviews Chi, 2009; Vass and Littleton, 2010; Webb, 2009).

The question as to how dialogues can be elicited is quite important and needs to be considered in this connection. Beyond simply letting students work together in pairs – which is a means to be located on the surface level of instruction – an effective way of improving the quality of collaborative thinking is the explicit structuring of the interaction. Examples are scripted collaboration, 'Reciprocal Teaching' (Palincsar and Brown, 1984) or 'Guided Reciprocal Peer Questioning' (King, 2008). A commonality all these techniques share is the fact that a set of cognitive and metacognitive strategies (e.g., sentence openers, posing questions with generic prompts, instructing students how to proceed in a dialogue; see Chi, 2009), which have to be applied in a more or less prescribed way, is provided. Another possibility for making learning environments more supportive for collaborative activities is to enrich them with technology. Well-designed *computer-based cognitive tools* provide users with both process-related and task-related means for thinking and communication, irrespective of whether they are to be applied in face-to-face or computer-mediated interaction. Functioning as mediating resources and cognitive tools for the representation, negotiation, and modeling of concepts and activities, educational software has the potential – by making conceptual structures and processes visible, accessible, and manipulable on a computer screen – to facilitate processes of sharing understanding, of achieving convergence and intersubjectivity and of argumentation (e.g., Noroozi et al., 2012; Reusser, 1993).

Although collaborative learning emphasizes the joint construction of knowledge among students, the teacher has still an important role to play. In relation to the coconstructive activities of learners this role can be described within the

didactic framework of 'cognitive apprenticeship' (Collins et al., 1989). According to the ethnographic model in which practices and principles of traditional craftsmanship are applied to cognitive learning activities, teachers, experts, or more capable peers provide guidance and support to learners as they participate as apprentices in authentic and task-related, structured social interactions. As opposed to a transmissionist view of instruction, teachers should provide aid in the intellectual development of students in ways that leave room for negotiation and joint expansion of meaning: (1) as scaffolds and role models for the behavior that students are expected to engage in; (2) as active participants in learning groups aiming at shaping the group's dialogue; (3) as monitors of coconstructive norms in social interactions in which negotiation of taken-as-shared meaning is essential (Webb, 2009); (4) as advocates of content-specific standards and of the achievement of convergence and intersubjectivity in understanding and problem solving.

Associated with this shift in the pedagogical orientation of teachers is a shift in the role of learners and the organization of classrooms. In the wake of a view that sees learning essentially as sociocultural interaction, classrooms should develop from aggregations of solo learners to communities engaged in coconstructive learning. That is, individuals should become acculturated members of a culture and community through collaboration and negotiation. Or, as Bruner (1986: p. 123) has put it: culture as "a *forum* for negotiating and renegotiating meaning and for explicating action … is constantly in process of being recreated as it is interpreted and renegotiated by its members."

Code Switching: Linguistic

Abstract

Though code-switching (CS) has been exceptionally well researched, controversy continues to reign over its identity, structure, and the rules governing its use. This article relates the state of the field to epistemological differences among researchers with respect to data, methods, the nature of evidence, and principles of scientific proof. Progress toward developing accountable theories of CS will be achieved once greater efforts are made to distinguish (1) apparently homologous but fundamentally distinct manifestations of language contact (currently subsumed under the label of CS) and (2) robust community-based usage patterns from isolated counterexamples.

Introduction

No outcome of language contact has garnered more scholarly attention than code-switching (CS). In its broadest sense, CS refers to the mixing of two or more languages in discourse. What prompts bilingual speakers to engage in such mixing? A variety of different motivations have been identified (e.g., Auer, 1995; Bhatt and Bolonyai, 2011; Gumperz, 1976/1982), often involving the bilingual abilities of the interlocutors (speak Croatian to grandma because she doesn't speak English), the context (call it *pizza* or *latte*, because there's no good English word for it), or the establishment of identity (as in emblematic CS), among many other sociocultural determinants. These contrast with what some have called 'true' or 'internally generated' CS (Gullberg et al., 2009), which has the particularity that two (or more) languages are spontaneously brought to bear in a single utterance with no change in interlocutor, situation, or even topic, i.e., with no external trigger. In some tightly knit bilingual communities, particularly Spanish–English communities in the United States, CS actually functions as a discourse *mode* (Pfaff, 1979; Poplack, 1980; Torres Cacoullos and Travis, 2015). This article surveys the linguistic treatment of such *intrasituational* switching.

Languages may, in principle, be combined at any level of linguistic structure, but community studies reveal that three are favored. These display varying degrees of syntactic involvement of the languages involved, and therefore require differing degrees of bilingual proficiency to achieve a 'felicitous' outcome (Poplack, 1980). The other-language element may be a *tag*, as in the Finnish–English example in (1), which can typically be freely inserted anywhere in the sentence with few if any syntactic repercussions; it may consist of a full *clause* or major sentence constituent, as in the French–English example in (2), where the syntactic requirements of either language are not a consideration, or it may appear *intrasententially* within the confines of a single sentence or constituent, as in the Spanish–English example in (3). It is this last type of CS that has attracted the most linguistic attention.

1. Mutta en mä viittinyt, *no way!* (9b.134)
   But not-1p. I bothered
   "But I'm not bothered, no way!" (Poplack et al., 1987, p. 394)
2. Je vas voir la fille, je dis, "*You got two tickets for Ottawa*?" (OH.105.3294)
   "I go see the girl, I say, 'you got two tickets for Ottawa?'" (Poplack and Dion, 2012, p. 300)
3. Pero los *grades are so bad* tambien, oiga. (088.10)
   "But the grades are so bad too, you know?" (Torres Cacoullos and Aaron, 2003, p. 291)

In combining languages intrasententially, various problems of incompatibility may arise. The most obvious ones derive from word order differences: under what conditions, if any, can the boundary between constituents ordered differently in two languages host a switch between them? Other potential combinatorial difficulties involve cross-language mismatches in grammatical categories, subcategorization patterns, and idiomatic expressions. Systematic examination of the spontaneous speech of bilinguals resident in a wide range of communities, however, suggests that the vast majority of sentences containing intrasentential CS remain 'grammatical,' in the sense that the appearance in them of two distinct languages does not contravene the syntax of either. This observation eventually led to the general consensus that these combinations are not effected randomly, as per earlier convictions (e.g., Weinreich, 1953/1968), but are rule governed. Discovery of the nature and locus of these rules, and the mechanisms by which they operate to produce well-formed, albeit 'mixed' utterances, has been the major goal of linguistic research on CS. Central questions include locating permissible switch sites, ascertaining the nature (hierarchical or linear, variable or categorical) of the constraints on switching, and determining when other-language items of one language (La) come to assume the structure of another (Lb) into which they are incorporated, or alternatively, retain their original La identity.

Close inspection of intrasentential mixing actually produced by bilingual speakers shows that the vast majority of other-language material appears in two major forms and results from two distinct processes. It may consist of a *lone* content word, such as those italicized in the Turkish–English example in (4) or be part of a *multiword fragment* of La in otherwise Lb discourse, as are the French and Wolof portions of (5). (All examples are reproduced verbatim from actual speaker utterances.)

4. … you go to visit your family … and visit your *nene* ('grandmother') and your *amcas* ('uncle-PL') and your *teyzes* ('aunt-PL') and that's about it really (EliF.153.5B) (Adalar and Tagliamonte, 1998, p. 154)
5. des fois da nga y xool un film avec des sous-titres en français (1.319)
   sometimes AUX you ASP watch a film with IND subtitles in French
   "Sometimes you watch a film with subtitles in French" (Poplack and Meechan, 1995, p. 213)

Lone grammatical elements (e.g., affixes, determiners, prepositions) are not generally involved. The La content words may have been *actively* drawn from La by the bilingual in the course of speaking Lb, or simply retrieved from an Lb lexical stock containing elements drawn from La at some point in the past, but now fully incorporated into the native Lb lexicon. (These are in fact equally accessible to monolingual speakers of Lb.) This is illustrated in (6), in which every 'English' noun is etymologically French. Such items, known as *loanwords*, are exceedingly common in languages of the world (e.g., Haspelmath and Tadmor, 2009).

6. The *judge* called on the *jury*, *lawyers*, and other *members* of the *court* to stand.

Loanwords are particularly instructive to students of language contact because of the evidence they provide on the synchronic result of the diachronic process of *borrowing*, which turns out to be the major strategy for language mixing. That evidence converges overwhelmingly on the fact that established loanwords come to assume the (morphosyntactic) properties of the language into which they were borrowed (the *recipient* language), following its morphological requirements and adopting its word order, while retaining none of their donor-language identity other than their etymology, and optionally, some elements of the phonology. Moreover, the available evidence suggests that this outcome is universal: identity with recipient-language morphosyntax is virtually always achieved, regardless of the typological features of the languages involved. CS, in contrast, retains the distinctive grammatical properties of its language of origin. As such, loanwords offer a crucial structural *benchmark* against which to identify mixed elements whose status is not so clear (see Section Evaluating CS Theories). (Because phonological integration is gradient, in both long-attested (e.g., *bar* [bɑɹ]) and more recent borrowings (Poplack, 2012; Poplack and Dion, 2012; Poplack et al., 1988), as well as in CS and unmixed speech more generally, on its own it is a poor predictor of language status.)

A 'Grammar' of CS

Bilinguals tend to switch intrasententially at certain (morpho) syntactic boundaries and not at others. Early efforts to explain these preferences proceeded by proscribing certain switch sites, e.g., between pronominal subjects and verbs or between conjunctions and their conjuncts (Gumperz, 1976/1982; Timm, 1975). However, these particular sites were soon reported to figure among the regular CS patterns of some bilingual communities (e.g., Pfaff, 1979; Poplack, 1981).

The first more general account of the distribution of CS stemmed from the observation that CS is favored at the kinds of syntactic boundaries which occur in both languages. The *Equivalence Constraint* (Poplack, 1980, 1981) states that switched sentences are made up of concatenated fragments of alternating languages, each of which is grammatical in its respective language of origin. The boundary between adjacent fragments occurs between two elements that are ordered in the same way in both languages, ensuring the linear coherence of sentence structure without omitting or duplicating lexical content (see also Lipski, 1977; Muysken, 2000; Pfaff, 1979).

That general principles, rather than atomistic constraints, govern CS is now widely accepted, though there is little consensus as to what they are or how they should be represented. Some research assumes that the mechanisms for language switching follow directly from general principles of (monolingual) grammar. Theories based on this assumption tend to appeal to abstract grammatical properties; since Klavans' (1985) proposal that CS was constrained by structural relations, the formal linguistic theories successively in vogue in the monolingual arena have each been extended to encompass CS. di Sciullo et al. (1986), for example, identified the relevant relations as C-command and government: CS cannot occur where a government relation holds, e.g., between verb and object, or preposition and NP complement. Later, the notion of feature agreement led to a parallel focus on feature matching in CS studies, as in the Functional Head Constraint (Belazi et al., 1994, 1995), which adds language choice to the features instantiated in functional and lexical categories, prohibiting CS where a mismatch occurs.

The distinction between lexical and functional categories is a hallmark of theories invoking the complement structure of individual lexical items to characterize permissible CS sites (e.g., Bentahila and Davies, 1983; Joshi, 1985; Mahootian, 1993). Perhaps the most detailed such model is the *Matrix Language Frame* model (e.g., Azuma, 1993; Myers-Scotton, 1993, 2002). Here, structural constraints on CS result from a complex interaction between a dominant 'matrix' language, which determines word order and supplies 'system' morphemes, and an 'embedded' language, which may only contribute content elements. The many exceptions to this generalization, notably all those consisting of 'embedded language islands' (i.e., the *multiword* fragments of La), are treated by a large number of subsidiary principles.

A more recent proposal in the minimalist framework dismisses the foregoing theories, not only as 'descriptively invalid,' but also as theoretically undesirable, because they posit CS-*specific* mechanisms. The 'Null Theory' (Mahootian, 1993; Mahootian and Santorini, 1996), like the minimalist approach (Chan, 2003, 2009; MacSwan, 1999, 2009), holds that there are no constraints or principles specific to CS in the language faculty of bilinguals. Following the dictate that only the 'minimal theoretical assumptions may be made to account for linguistic data,' and 'privileging more simplistic and elegant accounts over complex and cumbersome ones,' MacSwan (2009, p. 325) proposed the *Phonetic Form Interface Condition* (PFIC) to account for a purported 'ban' on CS in word-internal and head-movement contexts.

The PFIC was rapidly deemed descriptively invalid in its own right, on the basis of counter evidence brought by

Schindler et al. (2008) and Legendre and Schindler (2010), who in turn adopt the Optimality-Theoretic (OT) framework advocated by Bhatt (1997) for bilingual syntax to propose that "CS emerges from the resolution of conflicting constraints," and that different patterns of CS result from alternative rankings of a small set of universal but violable constraints. According to its proponents, Optimality Theory would explain why certain language pairs seem to violate constraints that account for CS in other language pairs. Though the methodology and specific assumptions differ, the Optimality-Theoretic approach is closest in spirit to the variationist perspective (e.g., Poplack, 1993), according to which a prediction like that made by the Equivalence Constraint is seen as universally applicable, but differentially instantiated according to the specific properties of the language pair – allowing CS between DET and noun in French–English (both of which feature DET + N order), for example, but prohibiting it between Swedish (N + DET) and English – and *variably* implemented.

As of this writing, however, not only is there no general consensus on what linguistic conditions constrain CS, but some scholars insist that the very search for them is futile (e.g., Bokamba, 1989; Gardner-Chloros and Edwards, 2004); others maintain that there are none (Chan, 2009; MacSwan, 1999; Mahootian, 1993), and still others, that constraints on CS may vary from one community to another (Bhatt, 1997; Muysken, 2000; Schindler et al., 2008).

There has been remarkably little cross-fertilization among these theories, and few researchers have accepted, let alone built upon, existing findings. Instead, scholarship in this field has consisted largely of successive dismissals of previous proposals, often on the basis of counter-evidence of uncertain provenance. Should the field proceed along the path of the last several decades, new models for CS will continue to be proposed and discarded, in tandem with new developments in (monolingual) syntactic theory. Whether any of these will come any closer than their predecessors to accounting for the data of actual CS productions will depend on the extent to which they succeed in addressing and resolving the following core issues, as well as the considerations outlined in Section Why Consensus Remains Elusive.

- Are all types of language mixture instantiations of the same process or do they result from different processes with distinct outcomes?
- Do lone other-language elements and multiword fragments behave in the same way and can they all be accommodated under a single theory?
- Is the process giving rise to multiword CS best characterized as alternation, insertion, or something else?
- Under what conditions are other-language elements integrated into a recipient language, and why do some of them resist integration?
- Are CS and borrowing related in the sense that the former gives rise to the latter?

Why Consensus Remains Elusive

Testing the fit of competing models against the data of CS should be a straightforward matter, especially since they often make competing predictions. But their disparate assumptions, goals, and domains of application have hindered such efforts. In what follows we attempt to pinpoint some of the reasons why consensus remains so elusive, despite decades of intense scholarly attention.

The Quest for an 'Optimal' Theory of CS

Lack of a widely accepted evaluation metric for CS theories, coupled with the range of their predictions, their volatility, and pervasive doubt over the extent to which they account for the data (and if so, which portions thereof), have all conspired in the general failure of any one to gain widespread acceptance. Section A 'Grammar' of CS detailed the tradition of appealing to the syntactic theories currently in vogue as models for CS behavior. But the assumption that bilingual syntax can be explained by general principles inferred from the study of monolingual grammar has not yet been substantiated. While formal theories of grammar may account well for monolingual language structure, including that of the monolingual fragments in CS discourse, there is no evidence to suggest that the act of *combining* two languages can be explained in the same way.

Theory-internal constraints play a more insidious role. For example, blind adherence to Occam's razor (e.g., Chan, 2009; MacSwan, 1999) and the quest for a 'unified account' (Gardner-Chloros, 2009; Myers Scotton, 2006; Winford, 2009) enjoin us to ignore fundamental differences among different manifestations of language contact, and to treat them all – at our peril! – as one and the same. The arbitrary requirement that an optimal theory must necessarily eschew CS-specific mechanisms diverts researchers from recognizing and attending to community trends. Different patterns of adapting monolingual resources in code-mixing strategies have been reported in different bilingual communities, even when the same language pair is involved; these are not predictable through purely linguistic considerations (Poplack, 1987; Muysken, 2000; Torres Cacoullos and Travis, 2015).

Variability, Probability, and Quantitative Reasoning

The field of contact linguistics has not fully acknowledged that the property of *inherent variability* (Labov, 1969), now generally accepted to characterize spoken language, extends as well to the bilingual context. The existence of variability renders the quest for 'categorical' constraints (obeyed 100% of the time) on CS futile. Instead, the behavior of bilingual speakers will be characterized by *patterns*, some very pervasive, others far more tenuous, as well as any number of outlier tokens, slips of the tongue, misspeakings, and even the odd speech error, *just as is the speech of monolinguals*. Distinguishing robust community patterns from the idiosyncratic utterance of any provenance requires in the first instance identifying a stable bilingual community where CS occurs regularly, and second, conducting accountable quantitative analyses of sufficiently large corpora of spontaneous CS production.

The Data

The data on which theories of CS have been built derive from a wide variety of (often incommensurable or even unidentified) sources. They may be intuited, invented, overheard, remembered, elicited in a laboratory setting, or observed during regular interactions among bilinguals in a bilingual speech community. The provenance of the many purportedly 'prohibited' CS which figure so prominently in CS theory building and demolition is likewise often unstated. Clearly, all kinds of data (with the exception of outright fabrications) have their place in CS research (e.g., Gullberg et al., 2009), but crucially, they are not interchangeable. The gold standard remains the (standard sociolinguistic-style) bilingual *corpus*: a principled assemblage of actual spontaneous productions of systematically sampled bilingual speakers resident in a well-defined bilingual speech community. Where these are stratified, randomized, and subjected to other basic requirements of social science research they yield invaluable information not only about the types and distribution of bilingual mixing strategies, but also about the associations they entertain with different sectors of the society and types of interaction.

A further consideration is that, from an analytical perspective, corpus data will almost always contain a variety of different types of language mixture. As detailed in Section Evaluating CS Theories, these do not necessarily behave in the same way. We cannot evaluate a theory of CS if we cannot assess its fit to a well-circumscribed body of unambiguous CS data.

Methods: Cherry-Picking versus Accountability

To be sure, many scholars of language contact have elicited bilingual data of varying degrees of spontaneity, and some have even constructed sizable corpora. But exploitation of this material is too often restricted to a few selected examples, or to declarations in lieu of demonstrations that all the data satisfy some constraint.

The real value of a corpus can be realized only through the *principle of accountability* (Labov, 1972), where every token of all constructions carrying out a certain role is counted and placed in statistical context. Only then are patterns discernable and general trends emergent from the complex production of spontaneous discourse. With few exceptions, however, linguistic analyses of CS have not been characterized by quantitative reasoning (in marked contrast to many psycholinguistic and neurolinguistic studies of the same topic). Remarkably, some linguistic researchers actually advocate *against* the use of quantitative methodology in the study of CS (Gardner Chloros, 2009). This is unfortunate, because where accountable analyses are *replicated*, striking commonalities have emerged (cf the papers in Poplack and Meechan, 1998a; Torres Cacoullos and Travis, 2015). These regularities are obscured by the emphasis accorded exceptions by the anecdotal reports that pervade the field.

The Pre-Eminence of the Counterexample

Indeed, the literature on CS is largely characterized by the 'rule-and-exception' paradigm. Each successive theory has been greeted with an onslaught of counterexamples, but very few have been systematically tested against principled collections of data of any sort. Even more rarely have the counterexamples been shown to represent quantitatively meaningful *patterns* of language use in a well-defined bilingual speech community. Instead, not only the theories but also tests of their applicability tend to be based on isolated examples, drawn from judgments, informant elicitation, and linguist introspection. Such data do not permit us to distinguish between the recurrent and systematic patterns of everyday interaction and utterances which may have been judged 'acceptable' in some sense, but which rarely or never occur. Even where theories are enthusiastically received, they seldom inspire the type of quantitative empirical work required to test their predictions on novel data sets. This lacuna, coupled with the tolerance for isolated counterexamples as a surrogate for proof, and the relative paucity of systematic quantitative analyses of large data sets and associated measures of significance and goodness of fit, is another key contributor to the lack of consensus. Failure to get on the bandwagon of replicable quantitative studies of spontaneous CS dooms the field to an endless round of rule-and-exception, minimizes our chances of arriving at cumulative findings, and hinders advancement of our understanding of CS.

Evaluating CS Theories

Assessment of the descriptive adequacy of a theory of CS requires that at least two methodological issues be resolved. One involves the proper classification of other-language phenomena; the other, systematic quantitative confrontation of the predictions of the theory with the data of actual bilingual behavior.

CS versus Borrowing

CS differs from the other major manifestation of language contact: *lexical borrowing*. Despite etymological identity with the donor language, established loanwords assume the morphological, syntactic, and often, phonological identity of the recipient language. They tend to be recurrent in the speech of the individual and widespread across the community. The stock of established loanwords is available to monolingual speakers of the recipient language, who access them normally along with the remainder of the recipient-language lexicon. Loanwords further differ from CS in that there is no involvement of the morphology, syntax, or phonology of the lexifier language.

Nonce Borrowing

It has now been established that borrowing is actually much more productive than implied above (e.g., Poplack and Dion, 2012; the papers in Poplack and Meechan, 1998a; Poplack et al., 1988). In particular, the social characteristics of recurrence and diffusion are not always satisfied. This results in what has been called, after Weinreich (1953/1968), *nonce borrowing* (Sankoff et al. 1990). Like its established counterpart, the nonce borrowing tends to involve lone lexical items,

generally major class content words, from La (acting here as donor language), and to assume the morphological, syntactic, and optionally, phonological identity of Lb, the recipient. Like CS, on the other hand, nonce borrowing is neither recurrent nor widespread, and involves *actively* drawing from La, necessarily requiring a certain level of bilingual competence. The Nonce Borrowing Hypothesis (Poplack, 2012; Sankoff et al. 1990) captures the empirical observation that speakers not only CS spontaneously, but may also *borrow* spontaneously, and these spontaneous borrowings assume the morphological and syntactic, and, optionally, phonological, identity of the recipient language *prior to* and *independently of* achieving the social characteristics of established loanwords (recurrence in the speech of the individual and diffusion across the community). The example in (7) illustrates how the nonce borrowing *coper* (<Eng. *cope*) is fully adapted morphologically and syntactically into French, despite having been unattested at the time of utterance, and produced only once by a single speaker.

7. Je serais pas capable de *coper* avec. (OH.037.1086)
   "I wouldn't be able to cope with it" (Poplack et al., 1988, p. 52)

In this, nonce borrowings mirror the linguistic behavior not only of established loanwords (e.g., *upgrader* 'to upgrade'), but of native counterparts (e.g., *échouer* 'to fail'). As noted in the Introduction, phonological integration, by virtue of its variability, is not diagnostic here.

Distinguishing Language Contact Phenomena

The classification of lone items is at the heart of a fundamental disagreement among CS researchers over (1) whether there is a distinction between CS and borrowing, (2) whether this should be formally recognized in a theory of CS, (3) whether these and other manifestations of language contact can even be identified in bilingual discourse, and (4) operational criteria for determining whether a given item was switched or borrowed. Researchers who consider lone other-language items to be CS tend to posit – for all CS – an *asymmetrical* relationship, in which one language dominates and other-language items are *inserted* (e.g., Joshi, 1985; Myers-Scotton, 1993). Where the class of CS is (in the first instance) limited to unambiguous *multiword* fragments, the languages are seen to alternate (Belazi et al., 1994; Sankoff, 1998a,b; Sankoff and Poplack, 1981; Woolford, 1983). Muysken (2000) admits both insertion and alternation as strategies.

Quantitative analysis of language mixing phenomena in both typologically similar and distinct language pairs shows that lone other-language items, especially major-class content words, are typically the most important component of mixed discourse by far (e.g., Berk-Seligson, 1986; Nortier, 1989; Treffers-Daller, 1994; Shin, 2002; among many others). The severe quantitative disproportions among single-word and multiword other-language items, coupled with the recent discovery (Poplack and Dion, 2012) that the vast majority of the former are integrated *abruptly* into recipient-language grammar, renders any analysis treating them as the same in effect a study of borrowing. They also explain the persistence of (descriptively inadequate) insertion analyses as blanket models for both CS and (nonce) borrowing. They do account for the bulk of the language mixing data, but not for the data of the less common multiword CS.

Contextualizing Language Contact Phenomena with Respect to Relevant Benchmarks

Distinguishing nonce borrowings from single-word CS is conceptually easy but methodologically difficult, especially when they surface bare or uninflected, giving no apparent indication of language membership. Insofar as CS and borrowing are based on some principled combination of elements of the monolingual (i.e., *unmixed)* vernaculars of the bilingual community, it is crucial to have as explicit an idea as possible of the structure of these vernaculars before concluding that a code-mixed element is behaving like one or the other. Such contextualization is usually omitted from CS research. The relevant monolingual benchmarks are not prescribed standards but the (unmixed) contact languages *as they are actually spoken*, and as noted above, spoken language is characterized by structural variability. In dealing with, rather than evading this variability, Sankoff et al. (1990) and Poplack and Meechan (1998b) developed a method to compare bilingual structures with the unmixed source languages of the same speakers. Making use of the framework of linguistic variation theory (Labov, 1969), the patterning of variant choice is used to determine their status. If the rate and distribution of, for example, case marking of the contentious lone other-language items show quantitative parallels to those of their counterparts in the (unmixed) recipient language, while at the same time differing from relevant patterns in the donor language, the lone other-language items are inferred to be largely *borrowed*, since only the grammar of the recipient language is operative. If they pattern with their counterparts in the (unmixed) donor language, while at the same time differing from the patterning in the unmixed recipient language, the lone other-language items must result from CS.

The last several decades have witnessed the accumulation of a coherent body of variationist studies on a large number of language pairs, involving large corpora of spontaneous bilingual speech, and a rich variety of morphosyntactic diagnostics such as determiner expression, adjective placement, case-marking, word order, and verb formation, among many others. These have demonstrated that the vast majority of lone items show the same fine details of quantitative conditioning of morphological and syntactic variability as dictionary-attested loanwords, both of which in turn parallel their unmixed counterparts in the recipient language (e.g., Aaron, 2014; Adalar and Tagliamonte, 1998; Blas Arroyo and Tricker, 2000; Ghafar Samar and Meechan, 1998; Poplack and Dion, 2012; Shin, 2002; Torres Cacoullos and Aaron, 2003; Torres Cacoullos and Travis, to appear). This tendency is apparent, regardless of the typological properties of the languages involved.

These quantitative studies have confirmed beyond any doubt that CS and borrowing are indeed two distinct processes, which are governed by different rules, and which – using the appropriate methodology – may be operationally distinguished as such (except in inherently language-neutral constructions). They have also converged on two

groundbreaking discoveries, correcting widely espoused assumptions in the field:

- Morphosyntactic integration of other-language items is independent of phonological integration. (Phonology, of both CS and borrowing, is variable, and thus cannot reliably be used to distinguish between them.)
- Morphosyntactic integration is not contingent on frequency and diffusion (i.e., achievement of loanword status), but rather occurs abruptly at the nonce borrowing phase.

Other recurrent findings to emerge from the systematic quantitative analysis of tens of thousands of tokens of spontaneous bilingual production data are

- the vast majority of all instances of language mixing are *single* other-language items and
- nearly all of them are immediately integrated morphologically and syntactically into the recipient language.

This means that a disproportionate number of lone other-language items have the linguistic features of established loanwords, independent of their social characteristics of frequency in the individual or recurrence across the community. Single-word CS, on the other hand, is exceedingly rare. (This finding does not license the a priori identification of *all* lone items as borrowings, however; the variationist literature offers clear discovery procedures to determine their status). Most important, the linguistic properties of CS – of whatever length – have been consistently shown in quantitative studies to contrast diametrically with those of borrowings: both the internal constituency and positioning in the clause of *borrowed* words come from the recipient language, while the internal constituency of CS is that of the language of origin, but its placement in the sentence tends to respect the word order requirements of *both* languages in the mix. This is the basic insight behind the Equivalence Constraint.

The Equivalence Constraint has been quantitatively verified as a major tendency in a number of language pairs, both typologically similar and different (e.g., Spanish–English (Poplack, 1980), Finnish–English (Poplack et al., 1987), Arabic–French (Naït M'Barek and Sankoff, 1988), Tamil–English (Sankoff, Poplack and Vanniarajan 1990), Fongbe–French, Wolof–French (Meechan and Poplack, 1995; Poplack and Meechan, 1995), Igbo–English (Eze, 1998), French–English (Turpin, 1998), and Ukrainian–English (Budzhak-Jones, 1998)). But most of the voluminous literature on CS, especially of the 'insertional' type, is based on data which represents, properly speaking, lexical borrowing. Thus, virtually all the published 'counterexamples' to the Equivalence Constraint involve single content words, which of course do not display the homologous word order that characterizes most true CS, but instead pattern syntactically and morphologically with the recipient language, just as predicted by the Nonce Borrowing Hypothesis (Poplack, 2012; Sankoff et al. 1990). Once the data of language mixing have been accurately circumscribed, and accountable analyses of large bodies of bilingual production data undertaken, nonce borrowing and CS under equivalence emerge as the quantitatively preponderant active mixing strategies employed in bilingual communities.

Future Directions

Over the past half-century, interest in CS has not only not abated, but to judge by the now vast amount of literature on the topic, it seems in fact to be growing. In welcome and instructive developments, approaches to its study have spread across linguistic subdisciplines from sociolinguistics to syntax to psycholinguistics, neurolinguistics, and beyond. In this context it is most disconcerting to the discipline that answers to the core *linguistic* questions continue to elude us.

This article has related the lack of consensus characterizing the linguistic study of CS to a number of epistemological problems. Foremost among them is failure to distinguish multiword CS from other types of language mixture, which, despite some similarities in surface manifestation, are fundamentally different mechanisms for combining languages. The current state of knowledge suggests that borrowing, nonce or established, is the major manifestation of language contact in most bilingual communities. Intrasentential CS involving multiword fragments of two or more languages is also attested in some communities. Achievement of consensus regarding an empirically verifiable characterization of the rules for *combining* such fragments within the sentence remains an important goal for CS research. To achieve it, we must improve the fit between theories and data. This would be facilitated by a broader empirical base.

In the first instance, existing theoretical, experimental, and anecdotal accounts of CS should be supplemented with many more large-scale empirical studies of actual bilingual behavior in a much wider variety of well-defined bilingual communities. As has been amply documented in the monolingual case, bilingual communities may exhibit widely different patterns of adapting monolingual resources in their code-mixing strategies, and these are not predictable through purely linguistic considerations. Thus, language pairs with the same typological characteristics do not necessarily display the same CS patterns in different communities (Poplack, 1987), the same language may behave differently when combined with different languages (Meechan and Poplack, 1995; Naït M'Barek and Sankoff, 1988; Nortier, 1989), and even the same language pair may display different patterning from one community to the next (Pfaff, 1979; Poplack, 1980; Torres Cacoullos and Travis, 2015). To account for these unruly facts, much more speaker-, context-, and community-based information must be incorporated into our analyses than has heretofore been the case. Consideration of the data of actual bilingual interactions in the context of the speech community in which they were produced would permit researchers to situate bilingual behavior with respect to the monolingual vernaculars implicated in language mixing, account for the disparate CS strategies that have evolved in different bilingual communities, and distinguish among incommensurable manifestations of bilingual language contact. Many more such studies are accumulating, but they are still in the minority.

To develop a theory of CS that is truly accountable to the facts, greater efforts must be made to tease apart the idiosyncratic and/or exceptional uses of individuals from community strategies. This can only be achieved via more accountable analyses of principled collections of naturally occurring bilingual data,

using accepted social-science standards of proof, including data-driven reports of rates of occurrence, conditioning of variant choice, and measures of statistical significance. This will necessarily involve distinguishing among the different manifestations of language contact and contextualizing the different mixing strategies with respect not only to each other, but crucially, to the monolingual benchmark varieties actually involved in the process (as opposed to some standard varieties thereof) as well.

We would then be in a position to carry out *more linguistic analyses* of the type of CS that all analysts can agree to constitute CS (i.e., multiword fragments of one language alternating with multiword fragments of another), free of the distorting effects of other manifestations of language contact. As detailed above, the latter, in particular lexical borrowing, have been demonstrated to far exceed unambiguous CS, and more importantly, display different linguistic behaviors from them, with the predictable result that including them in the pool of CS can only blur their structure. Recall that the major goal of linguistic analyses is to uncover, not the *constitution* of CS, which is already well understood (it corresponds exactly to that of its language of origin), but rather the *positioning* of CS in the sentence. Only by paying close attention to the directions outlined above, in conjunction with more experimental studies on multiword fragments, can we hope to achieve a true understanding of this endlessly fascinating recourse uniquely available to bilinguals.

Coeducation and Single-Sex Schooling

Sum Kwing Cheung, Early Childhood and Elementary Education Division, School of Continuing Education, Hong Kong Baptist University, HKSAR, China

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In many countries, coeducation schooling is predominant today, though single-sex schooling was once the norm in history. From the 1960s to 2010s, dozens of studies have been conducted to compare the relative effects of single-sex to coeducation schooling on students' academic- and career-related outcomes, as well as affective and social development. At its root, the controversy centers on the issue of gender equity in education. Despite its abundant literature, inconsistent findings were observed, and some findings were confounded by selection and school quality effects. Future studies can therefore investigate more carefully in which context single-sex schooling can be effective.

Coeducation and Single-Sex Schooling

Coeducation schooling, also called mixed-sex schooling, is the practice of educating males and females together. Single-sex schooling, on the other hand, refers to a form of education in which the two sexes are separated when teaching is conducted. It can be implemented at the school level (i.e., all-girls and all-boys schools) or classroom level only (i.e., single-sex classes for some or all subjects within coeducational schools) (Wiseman, 2008).

Among past literature, the debate on coeducation vs single-sex schooling often centers on the issue of how gender equity can be achieved in education. In the following, I would first describe the prevalence of coeducation and single-sex schooling around the world, followed by an outline of research trends in the literature on coeducation and single-sex schooling. Then, I would review empirical studies on the relative effects of single-sex to coeducation schooling on students' academic- and career-related outcomes, as well as affective and social development. Finally, I would conclude the article with a discussion on the limitations of existing studies and directions for future research in the field.

Prevalence of Coeducation and Single-Sex Schooling

Over the history of many countries, single-sex schooling had once been the norm. Nonetheless, its dominant position was later replaced by coeducation schooling. For example, in the United States, formal schooling was offered exclusively to boys at the beginning (Bracey, 2006). Later, during the post-Revolutionary War years, in response to the call for more systematic schooling for females by the public, girls started to have the chance to attend elementary schools in a sex-segregated manner (Salomone, 2003). In the mid-nineteenth century, common schooling for the masses began to take place; and coeducation schooling gradually became widespread, because it was often more economic to run schools for boys and girls to attend together than for a particular sex to attend (Anfara and Mertens, 2008; Shmurak, 1998). In 1972, with the passage of Title IX legislation, the setup of new single-sex public schools and classes was restricted (Bracey, 2006). Since then, single-sex schooling retained in the private and denominational sector only (Anfara and Mertens, 2008). Similarly, in England, receiving education at school was the privilege of boys of the wealthy in the early nineteenth century; and more schools for girls were established starting from the late nineteenth century (Leonard, 2006). However, unlike the case of the United States, the introduction of mass education in the nineteenth century led to the establishment of many single-sex schools (Leonard, 2006). It was only until the mid-twentieth century, when many selective secondary schools were replaced by large comprehensive schools, coeducation schooling began to become pervasive in England (Leonard, 2006).

Nowadays, coeducation schooling remains predominant in many parts of the world. Single-sex schooling occurs, but its prevalence varies considerably across countries. For example, in a study on the prevalence of sex-segregated eighth grade mathematics classrooms across 46 nations, Wiseman (2008) found that the level of sex segregation was nil in 12 nations (e.g., Sweden, Norway, Romania), very low (about 1–10% of schools) in 17 nations (e.g., the United States, South Africa, Japan, the Netherlands), moderate (about 15–20% of schools) in seven nations (e.g., Malaysia, Australia, Singapore, England), and high (about 25–100% of schools) in 10 nations (e.g., Israel, New Zealand). In the high sex-segregated group, eight nations (e.g., Egypt, Jordan, Iran, Saudi Arabia) even had sex segregation in more than half of the schools (Wiseman, 2008). In general, these variations in the rates of single-sex schooling arose from a wide array of sociocultural, economic, and political factors (Wiseman, 2008). For example, in countries like Australia, Singapore, and New Zealand, the practice of single-sex schooling was the legacy of colonialism and extensive borrowing of educational policies when implementing mass education (Wiseman, 2008). Nevertheless, it should be noted that the figures provided by Wiseman (2008) were only rough estimates of the prevalence of single-sex schooling in the aforementioned nations, because the percentage of single-sex schooling might vary by the level of education.

In recent years, single-sex schooling begins to return back to the educational landscape in the United States; and there have been a growing number of single-sex classes and schools (Hayes et al., 2011). The major reason is that the Title IX regulations had been amended in 2006, and single-sex education opportunities are now permitted in public schools

(Hayes et al., 2011). Therefore, it is generally expected that single-sex schooling would continue to blossom in the United States in the next decade (Hayes et al., 2011).

Trends in Research on the Effects of Coeducation and Single-Sex Schooling

As proposed by the National Association for Single Sex Public Education (NASSPE) in 2013, research studies that compared the effects of coeducation with single-sex schooling can broadly be classified into three types. The first type is nationwide studies, which involved samples of thousands of students or above (NASSPE, 2013). One example is the study on 2954 high school students' academic attainments in England conducted by Spielhofer, O'Donnell, Benton, Schagen, and Schagen from the National Foundation for Educational Research team in 2002. To address the problem that students are not randomly assigned to attend coeducation and single-sex schools, some researchers would develop samples for their research studies by randomly selecting schools or students from these large databases (Salomone, 2003). The second type is 'before and after' studies, which compared students' performance before and after the introduction of single-sex classes in particular schools (NASSPE, 2013). Since the same schools are involved when making comparisons, the effects of extraneous variables related to school characteristics are supposed to be eliminated in this type of studies (NASSPE, 2013). Streitmatter (1999, as cited in Mael et al., 2005), for example, had published a study of this type to investigate female students' attitudinal changes after they had participated in a single-sex class in coeducational public schools. The third type of studies is smaller-scale scientific studies that are commonly found in academic journals (NASSPE, 2013). Though the pool of participants involved in these studies was relatively smaller as compared to those involved in nationwide studies, researchers of these studies would adopt a number of statistical techniques to control the effects of extraneous variables (e.g., student–teacher ratios, school climate) when conducting data analyses (NASSPE, 2013; Salomone, 2003).

In the mid-nineteenth century, when coeducation schooling began to spread throughout the United States, there was an emerging controversy over the advantages and disadvantages of coeducation schooling (Shmurak, 1998). Feminists at that time generally supported the implementation of coeducation schooling because they feared that gender equality could not be achieved if separate schools were run for boys and girls (Shmurak, 1998). Other proponents of coeducation schooling also suggested that with the presence of the members of the other sex, boys showed better behaviors and girls became more independent (Shmurak, 1998). Middle- and upper-class parents, however, were reluctant to send their daughters to coeducation schools, because they did not want their daughters to be in touch with sons of the lower classes (Shmurak, 1998). Despite their concerns, the majority was inclined to coeducation schooling (Shmurak, 1998).

In the late 1960s and early 1970s, the feminist movement sparked off a debate on the advantages and disadvantages of coeducation schooling, which sustained till late 1980s and early 1990s (Shmurak, 1998). On the one hand, proponents of coeducation schooling advocated that coeducation schooling provided a happier learning atmosphere and promoted optimal adjustment to life (Gill, 2004), as students from coeducation schools were found to have more pleasurable social contacts and better interactions with members of the other sex (Gill, 2004; Leonard, 2006; Mael et al., 2005). On the other hand, feminists criticized that girls were often disadvantaged in coeducation schooling environments (Gill, 2004; Shmurak, 1998). As support for their claim, they demonstrated that in mixed-sex classrooms, girls received less attention from teachers, acted as school captains less often, and involved less in team sports (Gill, 2004). Girls were also found to receive sex-stereotyped advice from counselors, which made them less likely to enroll in mathematics and science courses (Gill, 2004; Shmurak, 1998).

In the meantime, in view of the situation that gender bias prevailed in coeducational classrooms, feminists began to regard single-sex schooling as a solution of achieving gender equity in education (Shmurak, 1998). From 1980s to 1990s, there was an increasing amount of research evidence demonstrating that single-sex schooling had some positive impacts on girls. For example, Lee and Bryk (1986, 1989, as cited in Shmurak, 1998) analyzed data from a longitudinal study conducted in the United States and found that girls from all-girls schools showed higher level of interest in mathematics and educational aspirations than their peers from coeducation schools. Riordan (1990, as cited in Shmurak, 1998) also found that girls from all-girls school performed better than in four curriculum-specific tests. However, there were some critics that Lee and Bryk did not control adequately the effects of background variables during their data analyses (Shmurak, 1998). They argued that after taking consideration of the preexisting differences among students, the achievement attainment gaps observed between girls from coeducation and single-sex schools would diminish (Salomone, 2003).

Since the late 1990s, there was an upsurge of concerns in countries like the United States, England, and Australia that boys were somehow being marginalized in the current schooling practices (Gill, 2004). Despite that some boys excelled well in coeducation schools, the dropout rate was higher among boys than girls; and teachers often complained about the disruptive behaviors of boys (Gill, 2004). Single-sex schooling is therefore regarded by some researchers (e.g., Gurian et al., 2009), a means to save boys from their crisis.

Effects of Coeducation and Single-Sex Schooling on Academic- and Career-Related Outcomes

The arguments put forward to support single-sex schooling primarily rest on two rationales (Hayes et al., 2011). The first rationale is the belief that there are some substantial differences in the biological predispositions between the two sexes; therefore, single-sex schooling environment can allow teachers to adopt more effective instructional strategies that best fit the learning abilities and styles of males and females, respectively (Hayes et al., 2011). Gurian et al. (2009), for example, suggested that teachers should provide more movement-based learning opportunities when educating boys because boys tend to have higher energy levels. On the other hand, given that

it is often very important for girls to feel belonged, teachers can create more collaborative and cooperative learning opportunities when educating girls (Gurian et al., 2009). Nevertheless, some researchers argued that innate differences between the two sexes in learning abilities and styles were negligible (Hayes et al., 2011). The second rationale is the belief that compared to coeducation schooling, single-sex schooling can provide an environment that is more conducive to the learning for the two sexes (Hayes et al., 2011). For example, there was some empirical evidence that in coeducation classrooms, boys tended to receive most of the teachers' attention whereas girls were often viewed and treated in a sexist manner by their teachers and peers (Hayes et al., 2011). All these factors, in turn, could have detrimental effects on girls' achievement attainments. Moreover, with the absence of members of the opposite sex, there were neither sexual tensions nor attractions in the classroom; and students could thus concentrate more on their learning (Bracey, 2006).

Over the last few decades, a number of research studies had been conducted to compare the effects of coeducation and single-sex schooling on students' academic- and career-related outcomes. Mixed results, however, were observed. Whereas some studies demonstrated that students from single-sex schools had better academic- and career-related outcomes than their peers from coeducation schools, some studies reported findings in the exactly opposite direction. Furthermore, there were some studies showing that the sex composition of the school did not affect students' academic- and career-related outcomes. In the remaining of the section, I would discuss the relations of coeducation and single-sex schooling to different outcomes of students in the academic and career aspects by making reference to the results of previous empirical studies.

The first area that often receives researchers' attention is students' attitudes toward different academic subjects and their subject choices (Gill, 2004). Advocates of single-sex schooling criticized that in coeducation schools, subjects were often polarized into the domains of males and females (e.g., mathematics, science, and technology as male subjects; language and history as female subjects) (Gill, 2004). This might, in turn, lower students' interest in subjects that belong to the domain of their own sex and their likelihood in choosing those subjects (Gill, 2004). Basically, a number of empirical studies provided support for this claim by demonstrating the effects of single-sex schooling on countering students' sex-stereotyped beliefs toward academic subjects. For example, there was evidence that girls who had attended single-sex science classes for a year showed more positive attitudes to science than girls who had only attended coeducation science classes (Gill, 2004). Some research findings also suggested that compared to girls from coeducation schools, girls from single-sex schools showed greater interest in mathematics (Shmurak, 1998). Furthermore, they were less likely to regard English as female subject and science as male subject, and were more likely to enroll in physics, chemistry, or biology (Shmurak, 1998; Spielhofer et al., 2002). Insignificant results, however, were sometimes reported. One example was the large-scale Australian study conducted by Ainley and Daly (2002, as cited in Gill, 2004), which did not find any significant differences between students from single-sex and coeducation schools in enrolling in physics courses. Herein, it should be noted that the presence or absence of differences in students' subject choice might sometimes be confounded by the subject-taking patterns offered by the school (Gill, 2004).

Another area that is often addressed when comparing the effects of single-sex and coeducation schooling is students' academic performance, especially girls' performance in subjects that are traditionally regarded as masculine (e.g., mathematics, science). Single-sex schooling, according to its advocates, can help improve students' educational outcomes, because pedagogical methods that are favored by a particular sex group can easily be implemented when the classroom is sex-segregated (Bracey, 2006). Nonetheless, empirical findings in this area were rather inconsistent. On the one hand, some classic studies conducted in the United States showed that compared to girls from coeducation Catholic schools, girls from single-sex Catholic school showed better academic achievements (Shmurak, 1998). On the other hand, Daly (1996, as cited in Shmurak, 1998) found that in Northern Ireland, girls from single-sex and coeducation schools did not differ in their scores on state examination in English and mathematics. In the United States, Shmurak (1998) also could not find any significant differences in SAT (a standardized test that is commonly used for admission to American colleges) between girls from single-sex and coeducation schools. Similarly, in New Zealand, Harker (2000, as cited in Mael et al., 2005) found that high school students from single-sex and coeducation schools did not differ in their scores on mathematics and science achievement tests. The findings of Spielhofer et al. (2002) in England revealed more complicated relations between the type of schooling and students' academic achievement. Girls in single-sex comprehensive schools have better academic achievements than those from coeducation comprehensive schools (Spielhofer et al., 2002). In contrast, boys from single-sex and mixed-sex comprehensive schools did not differ in their academic performance, though boys from single-sex grammar schools had significantly better academic performance than boys from coeducation grammar schools (Spielhofer et al., 2002).

The third area that researchers in the field focus on is students' classroom behaviors and general attitudes to school. Proponents of single-sex schooling often criticize that in coeducation classrooms, sexism is common during teacher–student as well as peer interactions (Bracey, 2006). In consequence, girls may suffer from a poor learning environment (Bracey, 2006). Such claims, however, are partially supported as well as rejected by past research findings. Apparently, girls could behave in a less sex-stereotypical manner in single-sex classrooms, but this did not necessarily lead to more favorable attitudes toward school. For example, though there was some research evidence that girls in single-sex classrooms displayed more risk-taking behaviors and asked more questions than girls in coeducation classrooms (Anfara and Mertens, 2008), Gill (1996, as cited in Shmurak, 1998) could not find any significant differences between girls from single-sex and coeducation schools in their attitudes toward school. Some research studies even found that students from coeducation schools held more positive attitudes to school than their peers from single-sex schools (Gill, 2004; Shmurak, 1998). One reason given by students from coeducation school was that they found interactions with opposite-sex members make school experiences more fun (Shmurak, 1998).

The last area that is of the interest of researchers in the field is students' educational and career aspirations. Supporters of single-sex schooling propose that in all-girls school, girls can get rid of sex stereotypes; and they are allowed to develop more ambitions in their educational and career goals (Bracey, 2006). Among past research findings, there are again no clear patterns. Though girls from single-sex schools were found to set higher educational goals to attain than girls from coeducation schools in some studies, such differences were not observed in some other studies (Mael et al., 2005; Shmurak, 1998). Shmurak (1998) even found in her longitudinal study that compared to girls who studied in single-sex schools before, girls who studied in coeducational schools before got into colleges at higher rank. In regard to career aspirations, some research studies showed that compared to girls from coeducation, girls from single-sex schools perceived the roles of women in the workplace in a less stereotyped manner and set higher yet more realistic career goals (Mael et al., 2005; Shmurak, 1998). Shmurak (1998), however, found that there were no significant differences between girls from single-sex and coeducation schools in their aspiration to careers that were traditionally male-dominated. Hoffnung (2011, as cited in Bigler and Signorella, 2011) also showed that graduates of all-girls and coeducation colleges did not differ in their attitudes toward women, career aspirations, marital timing as well as family planning.

In sum, though there are some studies documenting the relative merits of single-sex over coeducation schooling on students' academic- and career-related outcomes, there seems to be no clear evidence that single-sex schooling is more superior than coeducation schooling all the times in every single aspect. The positive effects of single-sex schooling on boys are also rarely stated.

Effects of Coeducation and Single-Sex Schooling on Affective and Social Development

Compared to the vast number of research studies that addressed the effects of coeducation and single-sex schooling on academic- and career-related outcomes, the literature on the effects of coeducation and single-sex schooling on affective and social development is rather sparse (Bigler and Signorella, 2011). Though theoretical arguments on the advantages of each type of schooling on students' affective and social development have sometimes been put forth, not all of the arguments have been validated by empirical studies (Bigler and Signorella, 2011). Among the arguments on the effects of coeducation and single-sex schooling on students' affective and social development that had been tested, just like the case of academic- and career-related outcomes, inconsistent findings were yielded. Below, I would discuss the arguments and empirical findings that are in support for each type of schooling in accordance with the area of concern they addressed.

The first issue that draws the attention of many researchers in the field is students' self-esteem. Claiming that sexism is prevalent in coeducation classrooms, proponents of single-sex schooling argued that students, in particular girls, can have higher self-esteem in sex-segregated classrooms (Gurian et al., 2009). Results of past research findings, however, are rather mixed. Some studies showed that students from single-sex schools reported higher levels of self-esteem than their peers from coeducation schools; whereas some other studies, including both cross-sectional and longitudinal studies, could not find any significant differences in the self-esteem level of girls from single-sex and coeducation schools (Anfara and Mertens, 2008; Shmurak, 1998). Some researchers thus proposed that significant relations between the type of schooling and students' self-esteem, if there was any, were more likely to be attributed to factors like students' academic abilities and socioeconomic status (Shmurak, 1998).

The second area that arouses researchers' interest is students' gender identity. Advocates of single-sex schooling suggested that girls can have more leadership opportunities in all-girls school, which in turn might help girls develop assertiveness (Campbell and Sanders, 2002; Shmurak, 1998). Moreover, some girls found that they could be themselves by the absence of boys in the classrooms (Shmurak, 1998). The study conducted by Sadker and Sadker (1994, as cited in Hayes et al., 2011), and Shmurak (1998) provided some empirical support for the claims. However, in the study of 6427 third-year secondary school students in Belgium by Brutsaert (1999), compared to girls from single-sex schools, girls from coeducation schools were found to be more likely to describe themselves as possessing more feminine as well as masculine traits.

The third issue that researchers center on is students' body image. Though advocates of single-sex schooling proposed that sexist incidents were less likely to occur in sex-segregated classrooms (Bracey, 2006), single-sex environments could promote more rigid definitions of 'masculinity' and 'femininity' in some aspects (Bigler and Signorella, 2011). One example of these aspects was body image. Some past research findings suggested that compared to girls from coeducation schools, girls from single-sex high schools were more dissatisfied with their body type, displayed more eating disorder behaviors, and showed a stronger desire for thinness (Mael et al., 2005; Shmurak, 1998). Davey, Jones, and Harris (2011, as cited in Bigler and Signorella, 2011), however, found that girls from single-sex and coeducation schools did not report any significant differences in their indices of body dissatisfaction and eating disorders, though the ideal body shape endorsed by girls from single-sex schools was thinner than that endorsed by girls from coeducation schools.

The last area of concern of researchers in the field is students' interpersonal relations. Proponents of coeducation schooling proposed that mixed-sex learning environments can promote 'optimal adjustment to life' because students would have experiences in interacting with members of the opposite sex (Gill, 2004). Several studies provided empirical support for this argument. For example, Harris (1986, as cited in Gill, 2004) showed that compared to graduates of single-sex schools, coeducation school graduates found interaction with opposite-sex members in the university easier. Foon (1988, as cited in Cheung and McBride-Chang, 2007) also found that coeducation school students were more affiliated with their peers than single-sex school students. Furthermore, in a study on Hong Kong 10th grade students' cross-sex friendship patterns by Cheung and McBride-Chang (2007), coeducation school students were found to have higher levels of friendship satisfaction toward their best cross-sex friends than single-sex school

students did. On the other hand, Brutsaert (2006) found that compared to feminine boys in coeducation schools, feminine boys in single-sex schools were less accepted by their peers.

In short, the literature on the effects of single-sex and coeducation schooling on students' affective and social development was not so abundant. Despite this, the empirical findings were not conclusive. There is some evidence of the merits of coeducation as well as single-sex schooling. **Table 1** summarized the relative merits of coeducation and single-sex schooling mentioned in the literature reviewed above.

Rethinking the Research Findings of the Effects of Coeducation and Single-Sex Schooling

Hayes et al. (2011) remarked that empirical studies that compared the effects of coeducation and single-sex schooling rarely employed random assignment of participants into the two types of school programs. In other words, many studies in the literature could not provide direct tests of the causal relations of the two types of school programs to the developmental outcomes of their students (Hayes et al., 2011). Their results should therefore be interpreted with caution, because they might be confounded by the following two effects.

The first one is the selection effects (Hayes et al., 2011). On the one hand, students who choose to study in single-sex schools may be more achievement-oriented than those who opt to study in coeducations schools (Hayes et al., 2011). On the other hand, the coeducation and single-sex schools under investigation may set different admission criteria (Hayes et al., 2011). As a result, the characteristics of students admitted to single-sex schools may be qualitatively different from those admitted to coeducation schools. For example, in England and Australia, single-sex schools were usually private schools with higher academic standards (Anfara and Mertens, 2008). They might therefore attract brighter students from more privileged backgrounds.

Table 1 Summary of the relative merits of coeducation and single-sex schooling mentioned in past literature

Type of schooling	*Relative merits*
Coeducation schooling	● Students held more positive attitudes toward school (Gill, 2004; Shmurak, 1998), showed more affiliation with their peers (Foon, 1988, as cited in Cheung and McBride-Chang, 2007), and found their best cross-sex friendship more satisfying (Cheung and McBride-Chang, 2007). Graduates found interaction with opposite-sex members easier (Harris, 1986, as cited in Gill, 2004). ● In particular, girls possessed more feminine and masculine traits (Brutsaert, 1999), felt more satisfied with their body type, displayed fewer eating disorder behaviors, and showed less desire for thinness (Mael et al., 2005; Shmurak, 1998).
Single-sex schooling	● Students held fewer sex-stereotyped beliefs as well as attitudes toward academic subjects (Gill, 2004; Shmurak, 1998), showed better academic performance (Shmurak, 1998; Spielhofer et al., 2002), and showed higher self-esteem (Anfara and Mertens, 2008; Shmurak, 1998). ● In particular, girls behaved in a less sex-stereotypical manner in classroom (Anfara and Mertens, 2008), set higher educational and career goals (Mael et al., 2005; Shmurak, 1998), and could be themselves more self-esteemed. (Sadker and Sadker, 1994, as cited in Hayes et al., 2011; Shmurak, 1998).

Note: Given that mixed results were yielded among past studies examining the effects of coeducation and single-sex schooling, the above merits were inconclusive and should be interpreted with great caution (e.g., by taking account of the context in which the studies were conducted).

The second one is the school quality effects (Hayes et al., 2011). Apart from the sex composition of students, the coeducation and single-sex schools under investigation in a study may vary greatly in other aspects of the school (e.g., academic standard, class size) (Bracey, 2006; Hayes et al., 2011). For example, Hayes et al. (2011) commented that many studies conducted in the United States involved comparison between students enrolled in private single-sex schools and public coeducational schools. However, private and public schools in the United States differed greatly in terms of their financial resources and other school characteristics (e.g., academic standards, class size) (Hayes et al., 2011). Thus, any observed differences in student outcomes can be caused by factors other than the sex composition of the school. For example, there were some speculations that the success of the California's experiment with single-sex schooling should, in fact, be attributed to the positive changes made in curriculum and instruction rather than sex composition of the school only (Anfara and Mertens, 2008).

Moreover, when interpreting research findings on the effects on single-sex and coeducation schooling, one should not generalize any observed effects too much. Instead, one should always pay attention to the context (including both the cultural and chronological contexts) in which the studies were conducted, as well as the educational level of the participants involved (i.e., preschool, elementary, secondary, or university). Given that the schooling system varies across countries and different countries have different cultural values, effects found in single-sex schools in the United States, for example, may not be necessarily existed in single-sex schools in other countries. Following the same reasoning, since some societal values have been evolved over the past few decades, it is possible that significant effects of single-sex schooling observed in 1980s, for instance, may magnify or diminish now. Similarly, one cannot assume that students at different ages have unique developmental characteristics, one cannot assume that the effectiveness of single-sex schooling on secondary education, for example, also applies in other levels of education.

To conclude, among past empirical findings, there is no clear evidence whether coeducation or single-sex schooling is a dominantly better option than the other. This perhaps suggests that researchers should stop asking the simple question, whether coeducation or single-sex schooling should be adopted. Instead, researchers should move a step further by investigating the interaction of the effects of coeducation and single-sex schooling with various contextual variables (Shmurak, 1998). In view of the above point, three possible directions for future studies are listed below.

First, in light of the mixed findings in the literature, researchers should admit that there are both advantages and

disadvantages for each type of schooling. To move on, researchers can investigate the relative benefits to the costs for each type of schooling in both the short and long run (Shmurak, 1998). Second, researchers can investigate which types of students can be benefited more from each type of schooling (Shmurak, 1998). Examples of student characteristics that may be relevant include students' academic abilities, socioeconomic status, and possessions of gender-related personality traits. Last, if single-sex schooling is thought to have some potential benefits of students, researchers can investigate how single-sex schooling can be implemented so as to maximize their benefits (Shmurak, 1998). For example, researchers can take into the consideration of the school or class size that is favorable for implementing single-sex schooling. The quality of teachers (including their beliefs, attitudes, and abilities to use various types of instructional strategies) may also be crucial factors for the success of single-sex schooling.

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

James D. Wright

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

This article is a revision of the previous edition article by H.C. Barrett, volume 7, pp. 4996–5000, © 2001, Elsevier Ltd.

Abstract

Cognition is the product of brain mechanisms that have been shaped by the evolutionary process. Understanding the form and function these mechanisms take, how they develop, and how they are distributed across species requires situating these mechanisms in an evolutionary context, and studying them using the diversity of methods available to the evolutionary sciences. Here we review how the mechanisms underlying cognition can be studied from an evolutionary point of view.

Evolutionary theory is widely agreed to be the best explanation for biological complexity and organization yet conceived, but the power of this theoretical approach has only in the last few decades been fully realized in explanations of human and nonhuman behavior (*see* Sociobiology: Overview; Sociobiology: History of). The behavior of humans and other animals is generated by functionally specialized nervous systems that develop and operate within the specific ecology of the organism (Tooby and Cosmides, 1992). Since the work of Niko Tinbergen, biologists have recognized that in order to fully understand an organism's behavior, explanations at several complementary (i.e., nonmutually exclusive) causal levels are required (Tinbergen, 1958).

On the proximate level, behaviors can be explained mechanistically as the product of neural activity, which itself responds to both external states, such as temperature, and internal ones, such as goals, emotion states, and physiological conditions. Neurobiology, cellular biology, and related disciplines have produced explanations for behaviors at this direct, causal level that are critical to understanding how behavior is proximally caused. Also at the proximate level are developmental explanations. An organism's psychological and physical traits are the result of developmental processes, initiated at conception, that shape the growing organism as a function of its interaction with the environment. Developmental biology and psychology have produced explanations of behavior that consider the timing of the appearance of adaptations over a single lifetime and the roles of learning and plasticity in shaping them (*see* Evolutionary Developmental Psychology).

Evolutionary or ultimate explanations are of two kinds. Phylogenetic explanations take into account the evolutionary history of descent with modification that has led a given organism to possess some traits and not others. This history can shape and constrain adaptations underlying behavior in powerful ways. Paleontologists, comparative anatomists, and geneticists have reconstructed the lineages of many species, and these phylogenies allow us to understand the evolution of brains and behavior in comparative and historical perspective (*see* Comparative Evolutionary Psychology: Current Status and a Proposal for a More Integrated Future; Comparative Method in Evolutionary Studies; Brain, Evolution of; Body, Evolution of). Another kind of ultimate explanation is functional or adaptive explanation, in which the traits of organisms are analyzed in terms of the roles they play in promoting survival and reproduction (fitness).

Functionalist or adaptationist approaches to cognition have made significant contributions to our understanding of how particular forms of behaviors and neural mechanisms reflect their adaptive functions. Until recently, researchers studying behavior have tended to focus exclusively on one level of analysis. More recent approaches to the evolution of cognition, such as evolutionary psychology, have sought to incorporate multiple levels of causation by explaining behavior not merely in adaptive terms (i.e., in terms of their immediate effects on fitness in current environments), but as the product of underlying proximate mechanisms, shaped by evolution, that might or might not produce adaptive behavior depending on the conditions under which they develop and operate.

Psychological Adaptations

An adaptationist approach to the mind begins with a simple premise: just like lungs, livers and flagella, brains are evolved organs with functional parts. Each of these parts, which are sometimes called psychological adaptations or modules, has evolved for something. They exist because they have been selected for, meaning they had positive effects on survival and reproduction over evolutionary time. They are 'for' something, in that they have consistently solved some adaptive problem, whether it was to discern light from darkness, to discriminate loud noises from soft ones, or to identify an object as food or as inedible. Any process in the mind that has evolved through natural selection to carry out an information-processing function can be regarded as a psychological adaptation (Barrett and Kurzban, 2006).

Formal descriptions of psychological adaptations include descriptions of their inputs, information-processing procedures, and outputs. The set of inputs that a psychological adaptation processes is called its domain, and adaptations vary in the kinds of information they have evolved to use. Similarly, the information-processing features of mechanisms can vary substantially, from the time series analyses performed by classical conditioning mechanisms, to Bayesian inference performed by systems underlying word learning and categorization, to if-then rules characterizing reasoning

systems. Finally, the outputs of psychological adaptations can exhibit special design; for example, different emotion systems cause a variety of diverse behavioral and physiological responses in organisms, from sexual attraction to nausea (*see* Emotion, Evolution of).

At the outset of the study of psychological adaptations, many researchers held that they should possess a common set of features, such as narrow information domains, encapsulation (inaccessibility to conscious processes), lack of environmental influences on development, and automaticity (Fodor, 1983). While some researchers continue to view psychological adaptations as strictly 'modular' in this sense, others argue that the hallmark of adaptation is likely to be functional diversity rather than functional uniformity (Barrett and Kurzban, 2006). This 'functional diversity' view of psychological adaptations is able to accommodate many types of mechanisms under the rubric of specialized adaptation, including mechanisms of learning and cultural transmission.

Domains

All the problems mentioned above are solved via the processing of information, but not all psychological processes use the same information. The information that a psychological mechanism uses is called its domain. For example, the visual system processes information about light energy transduced by photoreceptors in the retina, whereas the auditory system processes information about sound waves transduced by the cochlea. Within vision, some mechanisms respond to color, whereas others respond to shape, and even more domain-specific mechanisms can exist, such as mechanisms specialized to process the configuration of facial features in humans. In each case, the mechanism was shaped by the evolutionary process because of the effects it had on the organism's survival and reproduction. Visual mechanisms, for example, evolved because of their benefits for detecting predators and mates, for spatial navigation, and so on.

The behavior of complex organisms such as humans is not likely to be carried out by a single, general-purpose mechanism. In brains, information processing is made more efficient by cognitive division of labor: delegating tasks among smaller subsystems, whose operations can be coordinated through hierarchical organization and feedback loops. The nervous system is therefore a mosaic of many evolved mechanisms, often with different evolutionary histories. However, the fact that brains are complex networks of neural tissue means that investigators often cannot distinguish one subsystem from the next using anatomy alone.

Methods for Investigating Psychological Adaptations

Laboratory and Naturalistic Experiments

The signature of natural selection is functional design, characterized by a fit between form and function. In the case of cognition, this means that the brain mechanisms that perform specific information-processing functions will exhibit processing features designed to carry out those functions. To investigate adaptive design, rigorous empirical methods from a variety of fields including cognitive psychology, developmental psychology, anthropology, and neuroscience are in order, because these methods allow some measure of control over the multitude of variables interacting within a thinking mind. Laboratory experiments are tightly constrained and often artificial, which has advantages and disadvantages. It is informative to complement laboratory studies of cognition with studies in the field, and across diverse settings. An advantage of field studies is increased ecological validity, i.e., resemblance of the task to the natural setting in which it evolved.

As an example, standard experimental methods from cognitive psychology have been used in ecologically valid contexts in work investigating sex differences in human spatial cognition. Silverman and Eals (1992) proposed that sex differences in human spatial cognition may reflect an ancestral division of labor between hunting and foraging. Prior work has shown that women are better than men at certain abstract spatial tasks involving memory for object location, but since most of the data were gleaned from laboratory experiments, ecological validity was lacking. New et al. (2007) studied spatial cognition in an outdoor setting in a farmers market in Southern California, and showed that women are more accurate than men when pointing in the direction of newly learned locations for food items, but that both men and women are equally good in locating calorically rich food items in the same market. This finding is consistent with the existence of two distinct adaptive mechanisms: one to rank the value of food resources and one to remember the locations of those resources. By approximating foraging in a simple, natural design with modest controls, New and colleagues were able to offer a stronger argument for functional design. While sex differences may exist in spatial foraging ability, they are attenuated when their caloric value is higher, consistent with a mechanism that prioritizes the location of high-value food resources above low-value ones. This example shows how the use of multiple methods, within and outside the lab, can be used to provide converging evidence for or against evolutionary hypotheses.

Neuropsychological Dissociations

Just as multiple functionally specific adaptations can independently solve problems that confront the organism, so too can they independently malfunction, to varying degrees. Much of our knowledge of neurology and neuroanatomy has come from studies that examine impairments associated with localized brain tissue damage. The fact that small amounts of damage can result in specific deficits or dissociations in cognitive ability is powerful evidence for specialized design in the brain. Prosopagnosia, for instance, is a specific dissociation that impairs the facial recognition system, rendering patients unable to recognize people they know from facial features alone, while leaving relatively intact social knowledge of those individuals and the ability to identify them through other cues such as voice, hair, and gait. However, there is debate regarding the exact nature of the mechanisms impaired in prosopagnosia, with some arguing that they are evolutionarily specialized for face recognition, and others arguing that they are specialized for developing expertise in object recognition, with faces as a special developmental case (Gauthier and Nelson, 2001;

Kanwisher, 2010). This debate illustrates an important feature of domain specificity. Mechanisms are not either 'domain specific' or 'domain general,' but rather, can be described in terms of the nature of their domain: faces and objects are both domains, albeit different ones.

Developmental Studies

One mistaken, though widely held, belief about psychological adaptations is that they cannot be shaped by developmental input: that they must be present at birth and develop identically across individuals (i.e., 'innate' in a narrow sense). Instead, virtually all adaptations exhibit some degree of plasticity, though they vary in the nature and degree of that plasticity (*see* Evolutionary Developmental Psychology). Thus, hypotheses about psychological adaptations should include descriptions of how the mechanism in question is proposed to develop. This would include age trajectories of development, as well as hypotheses about how the mechanism in question might vary across developmental environments. For example, experiments with infants suggest that some mechanisms, such as mechanisms underlying the perception of objects, are thought to develop early in childhood, and similarly across children (Spelke, 1990). Other mechanisms, such as mechanisms shaping notions of fairness and moral judgment, appear to develop later, and can vary significantly depending on the culture in which the child is raised (House et al., 2013). This suggests that controlled studies across ages and populations are necessary to test hypotheses about the adaptive nature of cognition.

Cross-Cultural Studies

Cultural variation in cognition does not necessarily imply that adaptations are not at work. Even physiological and morphological traits that have been clearly shaped by natural selection, such as the immune system and the heart, vary across individuals. In the case of cognitive mechanisms, learning and other forms of external input are likely to play a role, in addition to – especially in the case of humans – culture (*see* Cultural Evolution: Overview). Thus, the existence or lack of variation does not by itself rule in or rule out the possibility that an aspect of cognition has been shaped by natural selection. Instead, theories of cognitive adaptations should include hypotheses about how and whether variation in the trait is expected to be manifest.

For example, there seems little doubt that spatial cognition in humans and other animals has been shaped by natural selection. In some cases, highly specialized spatial navigation systems are known to exist, such as dead reckoning in ants (Gallistel, 1990) and celestial navigation in indigo buntings (Emlen, 1975). Even in these cases, however, environmental input and learning play a key role: for example, the bunting celestial navigation system is calibrated through repeated exposure to the night sky during the course of development. In the case of humans, cross-cultural studies have shown that language is likely to play an important role in shaping some aspects of spatial cognition. For example, speakers of languages that customarily use absolute instead of body-centered frames of reference (equivalent to using, e.g., 'north' versus 'south' instead of 'left' and 'right') show greater awareness of their orientation relative to environmental landmarks and frames of reference (Levinson, 2003). This cross-cultural variation does not suggest that human spatial cognition is not the product of adaptations; it does, however, suggest that these adaptations are shaped by linguistic and/or other experiential input. More broadly, dimensions of cross-cultural variation, or lack thereof, are important sources of evidence for testing specific hypotheses about the features of psychological adaptations.

Cross-Species Comparisons

As Darwin recognized, adaptations evolve through descent with modification, and can therefore exhibit homologies, or similarities across species as a result of descent from common ancestors. On the other hand, specific taxa can have derived traits or traits that are unique to the taxon (and therefore do not have homologs in other taxa). And finally, distantly related taxa may share analogous versions of traits – traits that are similar – not due to common ancestry, but due to convergent evolution to solve similar adaptive problems. Because of this, the comparative method – comparing traits across species – is an important source of evidence for testing hypotheses about psychological adaptations, including hypotheses about their functions and evolutionary origins (*see* Comparative Method in Evolutionary Studies). Among the earliest cross-species comparisons were Darwin's analyses of similarities and differences in emotional expression across species.

An example of recent comparative work on psychological mechanisms is research examining the nature of prosociality, or cooperation, in humans and other great apes (*see* Human Cooperation, Evolution of). Key to this work are methods that can be compared across taxa, such as simple choices of how to allocate resources between oneself and a social partner (Silk et al., 2005). This work provides evidence for both similarities and differences in prosocial decision-making between humans and our closest relatives, suggesting some homologies and other derived features in humans. For example, humans and other primates respond prosocially to some signs of need, but only humans perform altruistic, prosocial acts in the absence of explicit signals of need from another party, suggesting a difference in the mechanisms underlying cooperation (Jaeggi et al., 2010).

Genes, Fossils, and Other Sources of Evidence

Finally, new technologies are beginning to provide data about cognitive evolution from novel sources. Genetic studies, for example, are beginning to provide evidence about genes that have diverged in humans and chimpanzees, and genes that have been under recent selection in our lineage. These include genes potentially related to language, motor control, brain connectivity, and other aspects of brain development. Studies of gene expression in humans and other animals also potentially provide a window into the nature and development of cognitive mechanisms, with a variety of studies showing substantial divergence in how genes are expressed in the brains of humans and other apes (Enard et al., 2002). Finally, paleoanthropological and paleoarchaeological evidence potentially bear on hypotheses about human cognition. For example,

anatomical evidence has been used to examine hypotheses about the origins of language in humans, and data from stone tools have been used to evaluate hypotheses about the cognitive mechanisms of early toolmakers, such as their working memory and spatial cognition (Wynn and Coolidge, 2004). Given the speed of technological change, it is likely that even more previously unknown sources of evidence will be brought to bear on our understanding of cognitive evolution.

A Case Study: Theory of Mind

Few cognitive adaptations have been investigated using all or most of the potential sources of evidence described above. For example, there are many claims about human universals that are supported by evidence from only a small and perhaps nonrepresentative sample of human societies. Ideally, multiple and converging sources of evidence are necessary in order to be confident about the nature of the evolved mechanisms underlying any particular aspect of cognition.

A useful case study for how diverse sources of evidence can be brought to bear in understanding the evolution of a cognitive ability is the case of 'Theory of Mind,' also variously known as mentalizing, mind reading, folk psychology, and psychological reasoning. Broadly, these terms refer to the ability to represent and make inferences about, and decisions based on, the mental states of others, such as their goals, desires, beliefs, intentions, attitudes, and motivations. While some theorists regard Theory of Mind as an 'all or none' capacity – you either have it or you don't – many researchers regard Theory of Mind as a continuum of abilities, distributed in different forms and combinations across species. Many agree that humans have particularly well-developed and elaborate Theory of Mind abilities, which develop early in childhood and are deployed across a range of contexts, from cooperation, to communication, to social learning.

A variety of sources of evidence have been used to examine how Theory of Mind is distributed across species, how it develops, how it operates on the neural level, and what happens when it is impaired. In humans, hundreds of studies have been conducted using the false belief task, a task designed to measure the ability to represent another's belief that is different from one's own (i.e., a false belief). The majority of studies have used so-called elicited false belief tasks in which children are asked to report about another's beliefs or behavior, and these generally show an age of development around four years, with substantial cross-cultural variation (Wellman et al., 2001). More recently, 'spontaneous' response tasks have shown that tracking of others' beliefs develops much earlier, and shows a similar developmental trajectory in early childhood across cultures (Barrett et al., 2013). Across species, no other species has been shown to track false beliefs, but our closest relatives, chimpanzees, represent the knowledge or ignorance of others and use it to predict their behavior (Call and Tomasello, 2008). Moreover, other mind-reading skills, such as the ability to track gaze, to understand when one has been seen, and to understand communicative intent, have been found in species ranging from scrub jays to domesticated dogs (Dally et al., 2006; Hare et al., 2002). Importantly, this work shows that the mind-reading skills of a species tend to be correlated with the adaptive problems facing the species, such as avoiding food theft (Dally et al., 2006). In humans, brain mapping studies have begun to reveal the neural substrates underlying Theory of Mind (Saxe and Powell, 2006). Impairment of mind-reading abilities, for example in autism, have been used to test hypotheses about the specificity of the underlying mechanisms (Baron-Cohen, 1995). In all, these studies converge on the conclusion that Theory of Mind is a specialized ability, produced by psychological adaptations that exhibit characteristic developmental timing and that are distributed across species in ways that make sense, given the social ecology of the species. While Theory of Mind is perhaps atypical in the diversity and breadth of techniques that have been used to study it, it provides a good example of how converging work across many fields can be used to understand the evolution of cognitive mechanisms.

Conclusion

There can be little doubt that the cognitive abilities of all species are products of the evolutionary process. They are the products of neural systems that have evolved through descent with modification, shaped by the success or failure of their information-processing properties over evolutionary time. The question, then, is not whether cognition is the product of evolution. Instead, we should ask how the mechanisms giving rise to a species' cognitive abilities have been shaped by the evolutionary process, how those mechanisms develop, and how they interact with the species' environment to produce the behaviors we observe.

In many ways, the study of cognitive evolution is still in its infancy. Contemporary psychology is only a little more than a century old, and evolutionary theory is only slightly older than that. The blending of the two, although it began in the work of Darwin, has only recently begun to take shape as a mainstream form of scientific inquiry. As a result, there is as yet no standard toolkit of methods for studying the evolution of cognitive mechanisms, but rather a diverse assortment of approaches drawn from the many branches of the biological and behavioral sciences. However, with the rise in popularity of evolutionary psychology and related fields, the possibility of a mature science of cognitive evolution is now in sight. Our map of the brain's evolved mechanisms still contains many blank spots, but the development of new and innovative ways of testing hypotheses about psychological adaptations suggests that much more will be known about the evolutionary basis of human cognition and that of other species, in the coming decades.

Cognition: Knowledge Spaces

Jean-Paul Doignon, Université Libre de Bruxelles, Bruxelles, Belgium

© 2015 Elsevier Ltd. All rights reserved.

Nomenclature

- $\mathcal{P}$ A relation on the ground set Q.
- $\varnothing$ The empty set.
- $\boldsymbol{\sigma}$ A mapping that associates to any item q the collection of clauses for q, that is, the various possible ways to acquire the mastery of q.
- $\boldsymbol{d}$ The symmetric-difference distance. For two sets K and L, the expression $d(K,L)$ gives the number of elements in which K and L differ.
- $K^{\mathcal{I}}$ The inner fringe of the knowledge state K, consisting of all items q in K such that $K\backslash\{q\}$ is again a knowledge state.
- $K^{\mathcal{O}}$ The outer fringe of the knowledge state K, consisting of all items q outside K such that $K\cup\{q\}$ is again a knowledge state.

Abstract

Knowledge assessment should be a central component in any computerized course. Procedures for knowledge assessment have been designed in the theoretical setting of knowledge spaces and learning spaces. They allow for a better outcome than just a crude number, giving deeper information on what is mastered together with advices for further study. Knowledge space theory thus offers a multidimensional extension of classical test theory. The present article introduces knowledge spaces under their combinatorial aspects, while the article Markov Processes in Learning Spaces describes the probabilistic aspects and the related assessment procedures.

This article introduces the combinatorial aspects of knowledge spaces and their special cases, learning spaces, by considering toy examples and stating precise definitions. It provides the required background for another article, *Markov Processes in Knowledge Spaces*, which introduces probabilistic aspects of the theory as well as knowledge assessment procedures.

Knowledge spaces are combinatorial models for encoding the conceptual organization of a given body of knowledge. Their theory leads to the design of efficient algorithms for assessing the concepts acquired by an individual in the given domain. Computer software implementing such algorithms are now in use in primary and secondary schools (e.g., Aleks). Their output is by far richer than just a crude number (e.g., 8 of 10) or mark (e.g., B). Indeed, it describes the present state of knowledge of the individual together with advice for further progress. Thus, by its combinatorial emphasis, knowledge space theory appears as a multidimensional generalization of classical test theory. It can also be applied to other settings (for instance, system failure analysis). Probabilistic extensions of the theory are covered in the article Markov Processes in Learning Spaces, while here the basic, deterministic concepts are introduced and some applications are sketched.

Organizing a Body of Knowledge

To start with an example, suppose that a teacher wants to assess the acquired capabilities of the pupils in a classroom as regards arithmetical multiplication. A list of items will be set up, starting from a simple question such as

$$\text{Item } a \quad 9 \times 8 = ?$$

and ending with a more complicate problem such as

$$\text{Item } b \quad \begin{array}{rr} & 278.9 \\ \times & 3.98 \\ \hline = & ? \end{array}$$

In classical practice, all items will be proposed to all pupils. The outcome of such a test boils down to a mark assigned to each pupil, which provides no other information than the number of correct answers. The performance of such a test is very poor. First, the pupils have to work on all problems (be these problems fairly easy or on the contrary out of reach for their actual competencies). Second, the marks convey a rather inaccurate description of the concepts and techniques mastered by each individual pupil.

These drawbacks are circumvented in oral testing. Here, the teacher can improve the examination procedure by taking into account answers previously collected in order to carefully select the next question to be asked. Moreover, this flexibility helps in building a more accurate description of the pupils' strengths and weaknesses. To illustrate these two points with our example, a teacher who checks that a pupil masters Item b will probably avoid asking Item a. On the other hand, if the pupil does not master Item b, other items will be proposed in order to diagnose which mistakes or misconceptions hamper the pupils' acquisitions. By carefully selecting each time the new item, the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.43049-7

teacher will gradually refine a description of the concepts and techniques mastered by the pupil. Such a description can be complemented with advice for remediation and a plan for further study.

Which are the factors that potentially make oral examination superior to written testing? Notice first that our analysis assumes a decomposition of the body of knowledge under testing into elementary pieces. To make things simple, we may suppose that each such piece corresponds to an item. Then, we assume some structure on the set of all these items. Back to our example, we declare Item a to be a prerequisite for Item b. As a consequence, we take for granted the following assertion:

> From a correct answer to Item b, we may surmise a correct answer to Item a (if the latter is asked).

In short, mastery of Item a is surmised from mastery of Item b. By contraposition, this rule is reformulated as

> a false answer to Item a implies a false answer to Item b.

Mathematically speaking, we have a (binary) relation $\mathcal{P}$ on the set Q of all items. The above assertions can now be written as $a\mathcal{P}b$. We call $\mathcal{P}$ the surmise relation on Q and assume that $\mathcal{P}$ is a quasi order, that is, $\mathcal{P}$ is reflexive ($q\mathcal{P}q$ holds for all q in Q) and transitive ($p\mathcal{P}q$ and $q\mathcal{P}r$ imply $p\mathcal{P}r$, for all $p, q, r \in Q$). Such a relation puts severe restrictions on the possible states of knowledge.

Knowledge States

Given the set Q of items, we identify the state of knowledge of an individual with the subset K of items that this person masters, thus $K \subseteq Q$. However, in view of the surmise relation $\mathcal{P}$, not every subset of Q can be a state of knowledge. Indeed, if a knowledge state contains q and $p\mathcal{P}q$ holds, then K must also contain p. We illustrate this with an example where $Q = \{a, b, c, d\}$ and $\mathcal{P}$ is the relation depicted in Figure 1. Subset $\{a, c\}$ is not a knowledge state since $b\mathcal{P}c$ holds, while $\{a, b, c\}$ is a knowledge state as can be checked. The full family $\mathcal{K}$ of knowledge states in this example is as follows:

$$\mathcal{K} = \{\varnothing, \{a\}, \{b\}, \{a, b\}, \{b, d\}, \{a, b, c\}, \{a, b, d\}, Q\}$$

where $\varnothing$ denotes the empty set. Notice $\{a, b\} \in \mathcal{K}$ and $\{b, d\} \in \mathcal{K}$, and also $\{a, b\} \cap \{b, d\} = \{b\} \in \mathcal{K}$.

This example can be used to illustrate some general properties of the family $\mathcal{K}$ of knowledge states of any surmise relation. The empty set $\varnothing$ and the whole set Q belong to $\mathcal{K}$; moreover, if $K, L \in \mathcal{K}$, then $K \cap L \in \mathcal{K}$ and $K \cup L \in \mathcal{K}$, that is, $\mathcal{K}$ is closed under intersection and under union. It turns out that these properties characterize families of subsets deduced from surmise relations. Indeed, this is a reformulation of Birkhoff's theorem (for infinite ground sets Q, closure under general intersection and union, not restricted to two subsets, need to be considered). We now argue that a more general setting is required.

Figure 1 Diagram of a surmise relation.

Knowledge Spaces

Suppose that a student produces correct solutions to systems of linear equations in several unknowns. The examiner cannot infer from this information whether the student has mastered computation of determinants, Gauss elimination procedure, the substitution scheme, or still another method of resolution. At least one of these methods is mastered, but which one is not clear from the student's answers. A generalization of the concept of a surmise relation is thus needed. Again, let Q be a set of items. To each item q, several subsets $C_1, C_2, \ldots, C_k$ of Q will be attached. These clauses for q represent all possible ways of acquiring the mastery of q; their number k may of course vary with q. We denote by σ the mapping associating to q the collection $\{C_1, C_2, \ldots, C_k\}$. For example, assume $Q = \{a, b, c, d\}$ and

$$\sigma(a) = \{\{a, b, c\}, \{a, d\}\} \quad [1]$$

$$\sigma(b) = \{\{b, c\}\} \quad [2]$$

$$\sigma(c) = \{\{c\}\} \quad [3]$$

$$\sigma(d) = \{\{d\}\} \quad [4]$$

The expression for $\sigma(a)$ thus encodes the following fact: mastery of item a implies mastery of a itself plus (b and c) or d.

In fact, a mapping σ is another formalization of an AND/OR graph from artificial intelligence. We will now make the concept more precise by taking into consideration four axioms (satisfied by the last example).

1. For each item q, there is at least one clause for q;
2. For each item q and each clause C for q, $q \in C$;
3. For each pair of items q, r and each clause C for q containing r, there is a clause D for r such that $D \subseteq C$;
4. Any two clauses C, C' for the same item are incomparable, i.e., neither $C \subset C'$ nor $C' \subset C$ hold.

Axiom (2) clearly generalizes the reflexivity axiom of a surmise relation, while axiom (3) extends transitivity. Axiom (4) translates our assumption that a clause for item q encodes a minimal way of acquiring the mastery of q.

Given a surmise system σ on Q, we define a knowledge state as any subset K of Q satisfying the following:

> For each item q in K, there is a clause C for q that is contained in K.

In the four-item example above, the collection $\mathcal{K}$ of all knowledge states is as follows:

$$\mathcal{K} = \{\varnothing, \{c\}, \{d\}, \{a, d\}, \{b, c\}, \{c, d\}, \{a, b, c\}, \{a, c, d\}, \{b, c, d\}, Q\}$$

Any surmise relation $\mathcal{P}$ on Q becomes a surmise system if we attach to any item q the single clause $C = \{r \in Q : r\mathcal{P}q\}$. Notice that the knowledge states defined from $\mathcal{P}$ coincide with those defined from the surmise system. We have moreover a neat variant of Birkhoff's theorem. Indeed, a family $\mathcal{K}$ of subsets of a finite set Q constitutes the collection of all knowledge states of a surmise system iff $\mathcal{K}$ is closed under union, and contains $\varnothing$ and Q (see Doignon and Falmagne, 1999, which presents also an infinite version of the result). A structure $(Q,\mathcal{K})$ satisfying these two conditions is called a knowledge space.

Closure under union is not required in most practical applications. A knowledge structure $(Q,\mathcal{K})$ is a finite set Q of items together with a family $\mathcal{K}$ of subsets of Q, with $\varnothing$ and Q belonging to $\mathcal{K}$. The elements of $\mathcal{K}$ are the knowledge states.

Wellgradedness

Knowledge assessment in this context assumes that a knowledge structure $(Q,\mathcal{K})$ has been built; the goal then is to design an algorithm that determines which state in $\mathcal{K}$ represents the knowledge of an actual student. This algorithm will efficiently select questions to be asked, thus reducing at each step the remaining possible states. Clearly, if all answers collected truly reflect the student's knowledge, the process will end after a few steps with a precise element of $\mathcal{K}$.

In real life, things are not so simple. Answers may be biased by lucky guesses (even if the items are not of the multiple-choice type this can happen) or by careless errors (a slight flaw in computation may alter the correctness). To take these undeterministic aspects into account, a probabilistic extension of the theory was conceived (see Markov Processes in Learning Spaces). It relies on a combinatorial notion that we now sketch.

After some time, an assessment procedure will have proposed one state K from $\mathcal{K}$ as the accurate representation in the structure $(Q,\mathcal{K})$ of the student's knowledge. A further answer of the student, say to item q, may call for a modification of K. If $q \notin K$ and q is correctly answered, then $K \cup \{q\}$ should become the state selected in $\mathcal{K}$ – provided $K \cup \{q\}$ belongs to $\mathcal{K}$. Similarly, if $q \in K$ and q is incorrectly answered, then $K \setminus \{q\}$ should be selected – provided it belongs to $\mathcal{K}$. We may not assume that always $K \cup \{q\}$ and $K \setminus \{q\}$ belong to $\mathcal{K}$, because otherwise $\mathcal{K}$ would be the collection of all subsets of Q (which is a much too large collection for our purposes). On the other hand, the assessment procedure should be able to explore the whole collection $\mathcal{K}$ by elementary steps consisting in the addition or deletion of a single item. To state a precise definition, we use for any two subsets K, L of Q their (symmetric-difference) distance

$$d(K,L) = \left|\{q \in Q : q \in K \setminus L \text{ or } q \in L \setminus K\}\right|$$

which counts the number of items q in which K and L differ. By definition, a knowledge structure $(Q,\mathcal{K})$ is well graded when for any two knowledge states K, L in $\mathcal{K}$ with $d(K,L) = h$, there exists a sequence $K = K_0, K_1, \ldots, K_h = L$ of states in $\mathcal{K}$ such that $d(K_j, L_{j+1}) = 1$ for $j = 0, 1, \ldots, h-1$.

For K, a state in a knowledge structure $(Q,\mathcal{K})$, we define the inner fringe and outer fringe of K as

$$K^{\mathcal{I}} = \{q \in K : K \setminus \{q\} \in \mathcal{K}\} \quad [5]$$

$$K^{\mathcal{O}} = \{q \in Q \setminus K : K \cup \{q\} \in \mathcal{K}\} \quad [6]$$

For example, if

$$\mathcal{K} = \{\varnothing, \{c\}, \{d\}, \{a,d\}, \{b,c\}, \{c,d\}, \{a,b,c\}, \{a,c,d\}, \{b,c,d\}, Q\}$$

then

$$\{a,d\}^{\mathcal{I}} = \{a\} \quad [7]$$

$$\{a,d\}^{\mathcal{O}} = \{c\} \quad [8]$$

In real-life applications, the outer fringe $K^{\mathcal{O}}$ collects those items that a student in knowledge state K could directly learn without any further prerequisite. This notion plays a crucial role in the design of the Aleks software.

It can be proved that a knowledge structure $(Q,\mathcal{K})$ is well graded iff any state in $\mathcal{K}$ is characterized by its inner and outer fringes. The latter condition can be stated as follows: if $K, L \in \mathcal{K}$, and $K^{\mathcal{I}} \subset L$, $K^{\mathcal{O}} \subset Q \setminus L$, then $K = L$.

Learning Spaces

Well-graded knowledge spaces are called learning spaces (cf. Falmagne and Doignon, 2011). They are also characterized by conditions of an intuitive nature. Let $\mathcal{K}$ be a collection of subsets, called states, of a finite set Q that contains $\varnothing$ and Q – that is, $(Q,\mathcal{K})$ is a knowledge structure. The pair $(Q,\mathcal{K})$ is a learning space if it moreover satisfies.

[L1] Learning smoothness. For any two states K, L such that $K \subset L$, there exists a finite chain of states

$$K = K_0 \subset K_1 \subset \cdots \subset K_p = L \quad [9]$$

such that $|K_i \setminus K_{i-1}| = 1$ for $1 \le i \le p$ (and so $|L \setminus K| = p$).

[L2] Learning consistency. If K, L are two states satisfying $K \subset L$ and q is an item such that $K \cup \{q\} \in \mathcal{K}$, then $L \cup \{q\} \in \mathcal{K}$.

The two conditions have simple interpretations in pedagogical language: [L1] if the actual state K of a learner is included in some other potential state L, then the learner can reach state L by mastering the missing items one at a time; [L2] knowing more does not prevent learning a new item.

Aleks

Aleks is a software initially designed at the University of California, Irvine, by a team headed by Jean-Claude Falmagne (other projects with similar goals were also conceived; see below the pointer to the bibliography). Now maintained and developed by a company with the same name, Aleks routinely assesses online the mathematical knowledge of pupils and students from kindergarten to bachelor programs. Presently used in schools, colleges, and universities, it covers arithmetic, algebra, precalculus, etc., and also, outside mathematics, statistics, business, etc. For a user, a session typically presents about 10 items, carefully selected on the basis of previously

acquired information on that particular user, and also on collected answers. At the end of the session, students receive information on their progress and advice for faster study (they can even access online explanation on relevant topics). Of course, the teacher is also informed of the monitoring process. Aleks is more than an assessment system, since it provides on demand the user with explanation and access to a dictionary. From experiments, it appears that students using the Aleks system progress much further in the material than students in a conventional class.

Bibliographic Orientation

The first publication on knowledge spaces was a 1985 paper by Doignon and Falmagne. The same authors published a survey book in 1999, and a revised, enlarged edition in 2011 under the title *Learning Spaces*. Various applications of the theory are covered in two books edited by Albert (1994) and by Albert and Lukas (1998). An evolutive and searchable bibliography is maintained by Cord Hockemeyer at the following Web address:

http://wundt.kfunigraz.ac.at/hockemeyer/bibliography.html

while the Aleks Website is at

Cognitive Aging

K Warner Schaie, University of Washington, Seattle, WA, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by K.W. Schaie, volume 3, pp. 2072–2075, © 2001, Elsevier Ltd.

Abstract

Cognitive aging is concerned with the experimental study of memory functions and language and the descriptive study of adult intellectual development. Methodological issues discussed include the issues of age-comparative versus age change designs and the role of response speed. Basic findings are presented on age differences in memory and language, age changes in intellectual competence, and on the question whether cognitive aging can be slowed or reversed by means of cognitive training.

Cognitive aging is concerned with age-related changes in adulthood in the basic processes of learning and memory, as well as the complex higher-order processes of language and intellectual competence or executive functioning. Although most of the literature has been concerned with explaining the mechanism of cognitive decline, there is also a substantial interest in issues such as compensation and the role of external support, including collaborative problem solving.

Definition of Cognitive Aging

There have been two distinct traditions in the study of cognitive aging. The first grew out of experimental child psychology while the second derives from psychometric roots.

Experimental Study of Memory Functions and Language

The concern in this literature is to explicate possible causal variables that would explain why many adults suffer memory loss and decline in the complex manipulation of language variables such as text processing. The typical approach here is to design experiments testing the effects of single variables in carefully controlled laboratory settings requiring only limited numbers of subjects. Because there is often little interest in individual differences, or population parameters, study participants.

Descriptive Study of Adult Intellectual Development

Descriptive studies of adult intellectual development often stem from the longitudinal follow-up of samples first assessed in childhood or adolescence (Schaie and Hofer, 2001). Other such studies may represent carefully stratified samples from defined populations, first assessed at a particular life stage, whether in early adulthood or in early old age. Although descriptive studies often begin as cross-sectional inquiries, they are most frequently conducted as longitudinal analyses since the primary interest of such studies is often in individual differences in intraindividual change or in the elucidation of typologies of individuals who follow different growth trajectories (*see* Adulthood: Dependency and Autonomy). These are frequently large sample studies, and the use of correlational or quasi-experimental approaches is typical (Baltes and Mayer, 1999; Schaie, 2013).

Methodological Issues

Age-Comparative versus Age Change Designs

Much of the experimental cognitive aging literature is based on age-comparative (or cross-sectional studies, which typically contrast a group of young adults, typically college students) with convenience samples of community-dwelling older adults in their 60s and 70s. It should be recognized that such comparisons are fraught by the problem that it is often unreasonable to assume that the two age groups can be adequately matched for other status variables that might provide a rival explanation for any observed age difference on the dependent variable. This creates particular problems for identifying the mechanisms that may be implicated in age-related decline from young adulthood into old age. Age-comparative designs are also inadequate in explaining individual differences in age changes (*see* Age Stratification). The latter can only be investigated by means of longitudinal paradigms (Ferrer and Ghisletta, 2011; Hofer and Sliwinski, 2006; Schaie, 1965, 1977, 2008, 2013; Sliwinski et al., 2010).

The Age-Cohort-Period Model

Early students of normal and pathological aging thought that the comparison of groups of individuals at different ages (cross-sectional data) could be used to predict and understand age changes within the same individuals (longitudinal data). A paradigm shift occurred when it was shown that such inference was not possible except under very unusual circumstances (Schaie, 1965, 1977, 2013).

The Model

The age-cohort-period model specifies that any age-related or time-dependent behavior can be assigned three temporal characteristics, such that

$$b\,(\text{Behavior}) \;=\; f\,(A + C + P)$$

where the behavior b is observed at the chronological age A, for individuals over the calendar period P who have entered the environment as members of cohort C. Just as is true for the relation among the physical variables of volume, pressure, and temperature, here also the third component can always be stated as a function of the other two components. Thus, $A = C + P$, $C = A + P$, and $P = A + C$. However, each of the three components may be of primary interest for some scientific questions in the developmental sciences, and one may therefore want to be able to estimate the specific contribution attributable to each component. In the behavioral sciences, in

particular, we typically want to differentiate effects that change across age (intraindividual change) from those effects that differ across cohorts or generations (interindividual differences).

Data Collection Strategies

Empirical studies in the developmental sciences involve age and/or cohort comparisons either at one point in time or at successive time intervals. Traditional strategies used for this purpose are represented by cross-sectional, longitudinal, and time-lag designs.

The cross-sectional strategy investigates the hypothesis that there are differences in one or more characteristics for samples drawn from different cohorts but measured at the same point in time. This strategy is most appropriate for the study of interindividual differences. Age differences in behavior at a particular point in historical time may be relevant for policy decisions that lead to differential societal responses regardless of the antecedent conditions responsible for the age differences. Age differences detected in a cross-sectional data set, however, are inextricably confounded with cohort differences. Since cross-sectional subsamples are measured only once, no information is available on intraindividual change. Unless there is independent evidence to suggest that older cohorts performed at the same level as younger cohorts at equivalent ages, it would be most parsimonious to assume, at least in comparisons of adult samples, that cross-sectional age differences represent estimates of cohort differences that may be either inflated or reduced by maturational changes occurring over a specified age range.

The longitudinal strategy investigates whether age-related changes have occurred within the same population cohort measured on two or more occasions. This strategy is appropriate when the investigator wishes to predict age differentiation in behavior that occurs over time. But longitudinal data do not always provide unambiguous estimates of intraindividual change. A single-cohort longitudinal study confounds age-related (maturational) change with period effects that are specific to the particular historical period over which the behavior is monitored. The period effects could either mask or grossly inflate estimates of maturational changes.

The time-lag strategy compares two or more samples of individuals drawn from successive cohorts at successive points in time at the same chronological age. The hypothesis tested is whether there are differences in a given behavior for samples of equal age but drawn at different points in time. This strategy is of particular interest to social and educational psychologists. It is particularly appropriate when one wishes to study performance of individuals of similar age in successive cohorts (e.g., comparing baby boomers with the preceding generation). The simple time-lag design confounds cohort effect with period effects and may provide inflated or reduced cohort estimates depending on whether the temporal interval between the cohorts represents a period of favorable or adverse environmental influences.

Sequential Strategies

Several alternative sequential strategies are available that might differentiate effects of maturational characteristic for a particular developmental period from the attainment of different levels of functioning attributable to differences in socialization and/or other life experiences characteristic for successive generation by assessing the behavior of more than one cohort over a given age range (Schaie, 1977; Schaie and Willis, 1999: Chapter 5; specific implications for the study of emotion are discussed in Schaie, 2001).

The term 'sequential' implies that the sampling strategy used to study generational differences must include the acquisition of a sequence of samples taken across several measurement occasions. Perhaps the most widely used sequential strategy is the 'cross-sequential' design, in which two or more cohorts are followed by an identical time period. This approach permits the direct comparison of longitudinal and cross-sectional data (provided that the calendar time ranges are similar for age and cohort). The advantage of this approach is that only two points in time are needed; hence the early appearance in the literature of studies using this design. For purposes of studying generational differences, however, this approach represents a 'model misspecification' because it does not allow comparing each cohort over the same age range.

Geropsychologists and other developmental scientists often find the cohort-sequential design of greatest interest because it explicitly differentiates intraindividual age changes that occur within a generation from interindividual differences between generations. This design also permits a check of the consistency of age functions over successive generations, thereby offering greater external validity than would be provided by a single-cohort longitudinal design. A cohort-sequential study consists of two or more generations (however defined) being followed over two or more similar age levels. The minimum design for such a study involves three measurement points, allowing each of two cohorts to be followed over the same age range (also see Sliwinski et al., 2010).

The Role of Response Speed

A number of theorists have argued that changes in the central nervous system are the primary common cause for the observed age-related declines in cognitive performance. In fact, there have been many published analyses that show a substantial reduction in age differences, if some measure or measures of reaction time or perceptual speed is partialled out of the relation between a given cognitive process and chronological age (Hartley, 2006; Madden, 2001; Salthouse, 1999). This issue is of particular concern because it is not clear whether the observed average increase in reaction time (generally assumed to be of the magnitude of approximately 1.6 from the early 20s to the late 60s), while reliably demonstrable in the laboratory, is of significance in many or most tasks of daily living.

Basic Findings from the Experimental Literature on Cognitive Aging

Most of this literature is cross-sectional in nature and usually consists of a comparison of convenience samples of young adults (often sophomore psychology students) and of community-dwelling older adults (often

participants in adult education programs). The major findings regarding age differences in cognitive performance include the following.

Memory

It is currently thought that older persons are at a disadvantage in retrieving information from memory when the information to be retrieved is complex and when there are few cues or other environmental support (*see* Brain Aging (Normal): Behavioral, Cognitive, and Personality Consequences). Hence, age differences are far greater in recall than in recognition of information. It is also thought that the magnitude of age difference in memory is far greater when a task involves effortful processing than when automatic processing is involved. Hence, greater age differences have been found for explicit than implicit memory. Older persons are also thought to have greater difficulty in integrating the context of information they are trying to remember. It is also thought that working memory capacity (i.e., the information kept in immediately accessible store) becomes reduced with increasing age. On the other hand, there is little evidence for age differences in long-term storage. Memory deficits occurring with age include nonverbal tasks such as memory for spatial location, faces, and actions and activities. Studies of prospective memory (i.e., remembering something to be done in the future) suggest that older people do well in remembering simple and event-based tasks, but are at a disadvantage when tasks become complex or are time-based. In sum, it appears that age differences are known to increase in magnitude as a function of the processing requirement of a given task (Hoyer and Verhaeghen, 2006; Salthouse, 1999; Smith, 1996). More recently, reductions in cortical volume particularly in the hypothalamus and reduction in functional brain activity have also been implicated in the reduction of memory function in the elderly (cf Nyberg and Bäckmann, 2011).

Language

Age-related differences in language behavior are closely related to the processes of encoding and retrieving verbal materials discussed above. But in addition there appear to be greater age differences in textual tasks that involve recent connections than in those that involve recollection of older connections.

Language production also seems to be adversely affected in older persons under intense time pressure. The interesting tip-of-the-tongue phenomenon involving word-finding difficulty, however, seems to be more likely with infrequently used words. Significant age differences have also been found in language planning, that is, in planning what one intends to say and how to say it during language production. Hence, older persons are more likely to engage in hesitations, false starts, and repetitions. Age-linked deficits in story recall are thought to be more of a general deficit in connection formation than in specific communication ability. Older persons tend to benefit from textual material that provides priming of association because it contains learned semantically linked information (McKay and Abrams, 1996; Thornton and Light, 2006).

Basic Findings from the Descriptive Literature on Age Changes in Intellectual Competence

Changes in intellectual competence over the adult life span have been studied primarily with either the Wechsler Intelligence Scale or with ability batteries derived from the Thurstonian Primary Mental Ability framework.

Distinctions are made between fluid abilities thought to be innate and crystallized abilities, which involve the utilization of culturally acquired knowledge (Cattell, 1963). More recently further distinctions have been introduced between the mechanics (or basic processes) of intellectual competence and the pragmatics that involve cultural mediation (Baltes et al., 1984).

What has been found in most longitudinal studies is that the adult life course of mental abilities is not uniform. The so-called fluid abilities (sometimes defined as cognitive mechanics or primitives) peak in early midlife and begin to decline in the early 60s. By contrast, crystallized abilities, or the pragmatics of intellectual competence that represent abilities acquired in a given cultural context (particularly verbal abilities), do not usually peak until the 50s are reached and begin to show significant decline only in the 70s and often show only minimal decline even in the 80s (Schaie, 2013). See **Figure 1**.

At any particular time, a cross-sectional snapshot may yield very different ability profiles because of the fact that subsequent population cohorts reach different asymptotes in midlife. For example, there has been a positive linear cohort trend in the twentieth century for inductive reasoning, the basic component of most problem-solving tasks, while there has been a negative trend in numeric skills. The magnitude of cohort differences in abilities since the 1950s has been comparable to the average age changes observed from young adulthood into the 70s. Hence, many older persons may appear to have declined markedly in comparison to young peers, even though the age difference may be primarily due to what might be called the obsolescence of earlier cohorts. See **Figure 2** for an example from the Seattle Longitudinal Study (Schaie, 1996, 2013).

Studies of individual differences suggest that while most persons have declined on some aspect of intellectual functioning from their own peak as the 60s are reached, that specific pattern of decline may well depend on complex patterns of individual life experience. Most healthy community-dwelling persons are able to maintain a high level of function until advanced old age (but see Baltes and Mayer, 1999 for the consequences of sensory dysfunctions). Because most tasks of daily living represent complex combinations of basic cognitive processes, many individuals can maintain their abilities above the minimally necessary threshold level for independent functioning by often rather complex compensatory processes (cf Baltes et al., 1984, 1999).

Can Cognitive Aging be Slowed or Reversed?

Once the course of adult intellectual development had been described and a number of antecedents of individual differences had been identified, it then became useful for researchers to think about ways in which normal intellectual

aging might be slowed or reversed (Stine-Morrow and Basak, 2011; Willis, 2001).

In a number of laboratories (primarily in the United States and in Germany), cognitive training programs have been developed that have been applied in the laboratory and more recently in cooperative multisite intervention trials. In contrast to training young children, where it can be assumed that new skills are conveyed, older adults are likely to have access to the skills being trained, but through disuse have lost their proficiency. Information from longitudinal studies is therefore particularly useful in distinguishing individuals who have declined from those who have remained stable. In the former, training is directed toward remediation of loss, while in the latter the enhancement of previous levels of functioning are sought with the intention of compensating for possibly cohort-based disadvantage of older persons.

Results from such cognitive interventions allow the conclusion that cognitive decline in old age, for many older persons, is likely to be a function of disuse rather than of the deterioration of the physiological or neural substrates of

Figure 3 Pre- and post-test findings at initial training and for the 7- and 14-year follow-up for the mental ability of inductive reasoning. From: Schaie, K.W., 2013. Developmental Influences on Adult Intelligence: The Seattle Longitudinal Study. Oxford University Press, New York, Figure 7.12, p. 221. Reproduced by permission of the publisher.

cognitive behavior. For example, a brief 5-hr training program for persons over 65 years of age resulted in average training gains of about one-half SD on the abilities of spatial orientation and inductive reasoning. Of those for whom significant decrement could be documented over a 14-year period, roughly 40% were returned to the level at which they had functioned when first studied. **Figure 3** shows pre- and post-test performance levels at initial training and at 7- and 14-year follow-up for the primary ability of inductive reasoning.

The analyses of structural relationships among the ability measures prior to and after training further allow the conclusion that training does not result in qualitative changes in ability structures and is thus highly specific to the targeted abilities (Schaie et al., 1987). A 7-year follow-up further demonstrated that those subjects who showed significant decline at initial training do remain at substantial advantage over untrained comparison groups (Schaie, 2013; Willis and Schaie, 1994).

Multiple site randomized trials of cognitive interventions have also been proved to be successful for programs seeking to enhance elders' performance on working memory, inductive reasoning, and speed of processing (e.g., Willis et al., 2006). It should be noted, moreover, that while cognitive training may improve performance in the elderly and may function to reduce effects of age decrement, such training will also be effective in enhancing the performance of young adults such that age differences tend to remain robust (cf Baltes and Kliegl, 1992). More recently, there has also been considerable interest on the effectiveness on collaborative learning in increasing cognitive performance and the question of extending cognitive training directly to activities of daily living.

Other Related Topics in Cognitive Aging

Much of the work on cognitive aging in the past has been concerned with age-related development in the mechanics and basic processes of cognition. It should be recognized that current attention in the study of cognitive aging is turning to the discovery of how these basic processes operate within more complex domains. Of particular interest here are the study of wisdom (e.g., Ardelt, 2011; Baltes and Staudinger, 1993; Sternberg, 1990), the application of the basic processes to social cognition (e.g., Staudinger, 1999), the development of expert systems (e.g., Charness and Bosman, 1990), and in everyday problem solving (Willis, 1996). The extensive literature on these topics is beyond the scope of this article.

Abstract

Situated at the intersection of cultural anthropology and cognitive science, the main concern of cognitive anthropology is to explain the mental representations and processes that make up cultural content. To this end, cognitive anthropologists combine approaches and methods from cognitive science with traditional ethnography and with techniques specifically developed for this very purpose. In this article, we first present a brief history of cognitive anthropology and of its core concepts and main methods. This is then rounded off with a perspective on the contributions that cognitive anthropology has to offer to cognitive science, including, among others, a concern not only with knowledge, but also with knowing, insights into the relation of language and thought, and a corrective for the (often untested) assumption of universality in cognitive processes.

One of the central objects of research in cultural anthropology is culture, in at least two respects: as cultural phenomena in a material sense, and as the cultural content based on mental representations. Although most cultural phenomena are public and thus accessible to ethnographic documentation, this is not true for cultural content that, instead, is largely situated inside people's heads. Explaining these mental representations and processes is the main concern of *cognitive anthropology*, and it is also where cultural anthropology intersects with other cognitive sciences. Together with cognitive psychology, philosophy, cognitive neuroscience, artificial intelligence, and linguistics, cognitive anthropology aims at understanding how people perceive, learn, process, store, and use knowledge of the world or, more generally, how the information received through the senses is interacting with thought processes (Gardner, 1985; Sternberg, 1999; Boden, 2006). In this alliance, however, anthropology has become a rather shadowy partner, which is unfortunate given that some of the theories emerging in cognitive science are also central to the concerns of anthropology.

The prevailing approach in the cognitive sciences is to analyze the human experience of the world and human thinking as information processing, including perception, motivation, emotion, problem solving, and memory. The objective is to make transparent, among other things, the mental faculties that enable all humans to internalize the social and cultural characteristics of the society into which they are born. And this interest overlaps substantially with central topics of anthropological research:

> …anthropologists' concerns place them right in the middle of the cognitive sciences, whether they like it or not, since it is cognitive scientists who have something to say about learning, memory and retrieval (Bloch, 1991, p. 184).

Cognitive anthropology seeks to contribute to these issues by combining cognitive science with traditional ethnography (Keesing, 1987; Tyler, 1969; Wassmann, 1994; Wassmann et al., 2011; Wassmann, n.d.; Bender and Beller, 2013). This bridge building is particularly valuable, given that the definitions of cognition (and many related concepts) used by mainstream anthropologists are often too sociological to be compatible with the approaches used by cognitive scientists. Lave (1988), for instance, sees cognition as originating in social practices of individuals, and Geertz (1973, p. 45) proposes that "thought is, in a great part anyway, a public activity." It can therefore not be surprising that anthropologists' theories of thinking, meaning, memory, and retrieval do not converge with those of cognitive scientists.

The limitations of the purely cultural focus was realized, for instance, by (psychologist) Rogoff and (anthropologist) Lave (1984), who advocated a shift away from Durkheim's cultural *représentation collective* toward a more central role for the individual. However, they also pointed out that relying on single individuals in special social roles (e.g., village principals) as 'omniscient informants' is not sufficient, but needs to be complemented by including individuals in nonexposed roles, the so-called plain folks. Even in common worlds, single lives differ (Keck, 1998). In fact, the tremendous variability of individual biographies renders the idea of one homogenous culture (at any scale, applied to an individual or the society) nonsensical.

Of course, the plain-folk individual in isolation, stripped of any cultural ties, is a limited model system too. And yet, it is this view that has been – and to some extent still is – characteristic of most cognitive science research. Apart from some socio-psychological strands, as in cross-cultural psychology (Berry et al., 2002; Mishra and Dasen, 2007), experimental work is often carried out on individuals in isolation and in highly nonnatural (but carefully controlled) environments. But this is only one of several characteristics that anthropologists consider critical. Another point for critique regards the computational model of the mind that has led scholars to neglect the interaction of content and process and the relevance of the social and material context of cognitive activities (Bender and Beller, 2011b, p. 1). Meanwhile, scholars have come to understand that cognition cannot be fully understood or explained without reference to a specific body (embodiment) and to a specific cultural environment (situatedness).

One of the implications of the computational model was the assumption that cognitive processes are universal – an

assumption compatible with the conception of 'psychic unity of humankind' proposed by anthropological founding fathers such as Franz Boas. Along the same lines, Cole and Scribner tried to identify basic capacities that seemed to be invariant across different cultural context. Although we may indeed assume that most cognitive and affective competencies do exist in all humans, the way in which they manifest as performance and emerge as 'cognitive styles' (Dasen and Mishra, 2010) depends on the cultural and ecological environment. This implies that the cognitive processes themselves may be subject to cultural influences (Atran and Medin, 2008; Bender and Beller, 2011b).

As a consequence, precise knowledge of and about such general cognitive competencies and processes is indispensable for any scientific field concerned with human biology and psychology or human nature and culture. It could also provide guidelines for finding the right balance between an individual and a cultural perspective on cognition and culture which, in turn, would be of the utmost relevance for both the field-working anthropologist and the brain-scanning neurobiologist. In order to understand better what cognitive anthropology has to offer in this debate, however, we first present a brief history of the discipline and an overview of some of its core concepts and methods.

From Ethnoscience to the Cognitive Sciences

The year of the 'cognitive revolution' to which, apart from cultural anthropology, various human sciences contributed, is considered to be 1956 (Gardner, 1985). In that year, a conference concerning information theory took place at the Massachusetts Institute of Technology, where Newell and Simon delivered a paper on computer programs. Miller presented his famous treatise, 'The Magical Number Seven,' and the 28-year-old Chomsky read excerpts from his thesis, 'Three Models of Language.' In the same year, Bruner's book *A Study of Thinking* came out, and two anthropologists, Goodenough and Lounsbury, published the first programmatical articles on what then came to be known as cognitive anthropology: 'Componential Analysis and the Study of Meaning' and 'A Semantic Analysis of the Pawnee Kinship Usage.'

With cognitive anthropology – or, more precisely, with the ethnoscientific phase of cognitive anthropology – a new field of research came to the fore. Its goal was to describe other cultures in their own conceptualization, that is, in *emic* terms, or 'frominside.' Because various cultures categorize the world differently and appear to apply different types of logic in dealing with it, these differences need to be recorded and analyzed to explore the differing cognitive worlds. The underlying question was an old one, posed by another founding father of anthropology, Malinowski: What does 'order out of chaos' look like? More precisely, scholars were interested in how (other) cultures label the things in their environments and how those labels are related to each other. The underlying assumption was that, with the help of cultural phenomena, the mental representations that make up the cultural content could also be understood.

Three Premises

Three premises formed the background of this ambitious program (see Dougherty, 1985):

Premise 1: Culture is Common (Shared) Knowledge

The first and most influential definition of culture as knowledge – and thus as, in principle, a *mental* phenomenon – was given by Goodenough:

> A society's culture consists of whatever it is one has to know or believe in order to operate in a manner acceptable to its members, and to do so in any role that they accept for any one of themselves.… It is the forms of things that people have in mind, their models for perceiving, relating, and otherwise interpreting them.… Culture does not exist of things, people, behaviour, or emotions, but in the forms or organizations of the things in the minds of people (1957, pp. 167–168).

Premise 2: Knowledge Systems Provide a Cultural Grammar

On the basis of the statements made by their informants, anthropologists inductively discover this abstract and shared knowledge as a systematic mental representation. In principle, this could be done with only one informant, just as learning a foreign language requires only one native speaker as one's teacher. The knowledge system of a culture is understood to be a conceptual model that embraces the organizational principles of the culture and the behavior of its members. In this sense, the model is a 'cultural grammar.'

Premise 3: Language is the Best Means of Access to Mental Phenomena

With the 'reduction of chaos,' certain phenomena and characteristics are selected from the environment as being significant are named and given a classificatory meaning. The main (but not the only) proof of a category's existence is its label, and this label conversely provides access to the category.

The equation of culture and knowledge initially proved to be very fruitful, and in the 1960s, ethnoscience experienced rapid success. Innumerable studies were published about terminologically densely structured individual fields, such as kinship, colors, ethnozoology, ethnobotany, or illness (for an overview, see D'Andrade, 1995). One succumbed, as it were, to the great theoretical temptation to reduce complex and ostensibly heterogeneous domains to a few rules (inclusion, exclusion, and intersection) and to present them as elegant models (taxonomies or paradigms; see below) that were looked upon as mental representations of individuals.

At the beginning of the 1970s, however, only a few studies of this descent were still published, and in 1972, Keesing felt justified to start a paper with the sentence: "Whatever happened to ethnoscience?" (1972, p. 299). Ironically, when, at the end of the 1950s, ethnoscience had taken over the phonological model from structural linguistics to become the focus in the 1960s, this same model had already given way in linguistics itself to Chomsky's new generative linguistics.

As a consequence, anthropology had to open up and turn toward modern trends in neighboring disciplines. Computer science exerted a particularly strong influence. When the first computer programs started to 'play' chess, cognitive

anthropologists adopted an information-processing approach and attempted to transfer the concept of programs to describe and explain the way in which culture is both structured and structuring human thinking and behavior. The underlying assumption was that cognitive processes could be modeled in the same way, regardless of whether they take place in humans, animals, or machines. In other words, the software was assumed to be the same everywhere, irrespective of the hardware in which it was processed.

Revised Premises

In light of this theoretical and conceptual reorientation, the three premises of ethnoscience had to be reconsidered and extended: While the basic question remained the same, namely, how knowledge is structured (to create 'order out of chaos'), the novel twist to it was where knowledge is sought and how it is represented.

Revised Premise 1: Turning Toward the Individual

With the insight that individual cognitive processes or representations cannot be directly inferred from cultural phenomena came a shift in focus away from the collective knowledge system as a whole (to be recorded as the ideal type) toward the scattered, variable knowledge acquired, memorized, and applied by individuals in their everyday lives.

Revised Premise 2: Turning Toward Operationalization Instead of Categorization

As soon as knowledge is no longer conceived of as an isolated, static system (that is, as 'grammar') but as revealing itself (verbally or nonverbally) in everyday use by individuals, many categories and semantic fields were regarded as fuzzy sets that lacked precise or fixed boundaries. These categories can be organized by best exemplars, or prototypes, or they can be organized according to what a person typically does in daily life: 'taskonomy,' instead of 'taxonomy.' *Taskonomies* refer to everyday cognition that a housewife needs when shopping, a milkman when distributing dairy products to his customers according to a certain pattern, a Yakan in the Philippines when entering a house correctly, and it is this everyday cognition that anthropologists then became interested in.

Revised Premise 3: Turning away from Language as the Only Instrument to Code Knowledge

Knowledge is expressed not only through language but also by means of actions and emotions. Habitual actions, in particular, can be very eloquent in revealing tacit knowledge. To describe stereotyped sequences of actions in certain situations, the computer scientist Schank and the social psychologist Abelson, in 1977, introduced the notion of *scripts*. Language remained of interest but was treated differently, no longer as a lexicon (or grammar) but as discourse from which inferences had to be drawn about the intended message. No longer was it assumed by default that the structure of knowledge (as represented in the mind) has to be language-like:

> Knowledge organized for efficiency in day-to-day practice is not only non-linguistic, but also not language-like in that it does not take a sentential logical form (Bloch, 1991, p. 189–190).

Some pushed this critique even further by calling for ignoring language more frequently because certain kinds of knowledge cannot be expressed linguistically, or only with great difficulty.

The fact that individuals and how they act in their daily lives are now in the focus of interest is a consequence of a paradigmatic shift. Cognition is no longer regarded as an expression of culture as a whole, abstracted from linguistic material, but as the mental activity of individuals who make flexible use of their knowledge in different contexts, in that they think, generalize, draw inferences, perceive, recognize, and categorize; analyze, combine, assess possibilities, solve problems, and make decisions; classify, differentiate, and choose; remember and master new situations. Although these activities are performed individually, or between individuals (Hutchins, 1995), they always and everywhere take place within culture.

The Representation of Knowledge

The most important models of representing knowledge in cognitive anthropology are briefly described below.

Taxonomy

The inner order of a semantic field (such as furniture or colors) depends on a small number of ordering principles that structure the lexical components (lexemes) of the field (e.g., 'table,' 'red'). The ordering principles are inclusion, exclusion (contrast), and intersection.

A taxonomy provides a description of such a semantic field; it lists the categories (lexemes) and shows how they are connected with each other: that is, according to the principles of exclusion and inclusion in hierarchic order. Categories at the same level *exclude* each other, whereas categories at the lower level are *included* in the categories at the higher level (Example: Table 1).

The grouping shows that dining tables are different from smokers' tables but that both are kinds of tables. Chairs, on the other hand, are distinguished from tables. The grouping does not say which are the distinguishing characteristics.

Paradigm

If a semantic field is structured according to the principle of intersection, we have a paradigm. Hierarchy, inclusion, and exclusion are missing; instead, the *distinctive features* (or criterial attributes) distinguish the categories. Paradigms are constructed by a componential analysis. A complete lexicon of a semantic

Table 1 Taxonomy

Table 2 Paradigm

		Sex	
		a1	*a2*
Generation	b1	Grandfather	Grandmother
	b2	Father	Mother
	b3	Ego	
	b4	Son	Daughter
	b5	Grandson	Granddaughter

field (e.g., blood relationship) is established and then those characteristics (components) are looked for, according to which the lexemes differ, for example, male and female in the dimension sex, or the distance from Ego in the dimension generation. Every single lexeme is now defined by a bundle of components. In a graphic representation, these components intersect at the defined lexeme (Example: Table 2).

Taxonomy and paradigm were consistently emic and were the classic models of ethnoscience. They were strongly idealized and understood as appropriate tools to characterize a culture. As we know today, however, they are only to a small degree cognitive and not really instruments of thinking.

Prototype

A prototype is the object within a category that is thought to be its best example. In the category furniture, for instance, chair is a better example than, say, radio. Of course we could define *furniture* as a category of objects having certain semantic characteristics or attributes in common (and whatever does not have these characteristics does not belong). However, this checklist definition does not allow any grading, such as a chair being a better example, more of a prototype of furniture, than radio (although both belong to the category of furniture). It may happen that there are no criterial attributes common to all parts (i.e., no semantic field, no class, according to ethnoscience) but only a large number of characteristics that may match some but by no means all category members. As a consequence, they only have a 'family resemblance' structure – a term Rosch and Mervis adopted from Wittgenstein. Following Lévi-Strauss, prototypes are particularly 'good to think' (Example: Table 3).

Script, Schema, and Cultural Model

The information theory approach forces the anthropologist to be explicit about what normally remains implicit, and some of this is captured by scripts. Scripts are used to represent and/or describe procedural knowledge, including the structure of the activities or events they represent. Scripts describe the tacit knowledge that enables us also to understand incomplete descriptions and suggestions; we automatically add what is missing by an inference process. Every situation requires specific knowledge and, accordingly, there are scripts for eating in a restaurant, playing football, and attending a birthday party. But not only our actions are based on scripts, our language is as well – a story told with all the details would be tedious.

Table 3 Prototypes

Prototype	*Category*
Chair	Furniture
Car	Vehicle
Orange	Fruit
Gun, etc.	Weapon, etc.

Example:
I am in New York and somebody asks me the way to Coney Island; I tell him to take the N-train to the terminus.
This instruction makes sense only "if this improperly specified algorithm can be filled out with a great deal of knowledge about how to walk, pay for the subway, get in the train and so on" (Schank and Abelson, 1977, p. 20).

If the typical characteristics of a situation are grasped – hence the stereotypical, the standard-like is stressed, but raised to a higher level of abstraction – we can talk about schemata and cultural models (which partially replace the older term, *folk models*). All the knowledge we acquire, remember, and communicate about this world is not a simple reflection of this world, nor does it consist of a series of categories (as ethnoscience assumed), but it is organized into different situation-relevant, prototypical, simplified sequences of events (Quinn and Holland, 1987, p. 32). What is more, these models are probabilistic and partial; they are actual frames we can also use to react to new situations. They are world-proposing "yet cannot be directly observed since they are not presented, but merely represented by the behavior of the people. They are models *of* the mind and in the mind" (D'Andrade, 1989, p. 824). The organizing principle behind these models is metonymy: a conspicuous part represents the whole (cf frame theory by Minsky, story grammar by Rumelhart).

Mental Images

Knowledge may also be represented by inner images. The image schema consists of schematized, simplified images. These images make comprehensible and literally imaginable physical objects or logical relationships that are otherwise difficult to conceptualize. The organizing principle behind them is the metaphor: through analogy, information from the physical world is introduced into the non-physical world.

Examples:
Rage can be imagined as a hot liquid in a container, evaporation as rising molecules springing out of the water like popcorn, and electricity as a crowd of people (in front of the gate of a stadium at a sports event) or as a flood forcing itself through some obstacle.

Trajectories for Future Research

A broad overview of current topics and trends in the field is given in *Companion to Cognitive Anthropology* (Kronenfeld et al.,

2011). Some of these trajectories, however, deserve explicit mentioning because they are closely related to the theoretical notions discussed in this article.

The theoretical developments of the structure of knowledge representations, as summarized in sections Prototype; Script, Schema, and Cultural Model; and Mental Images, allow us to understand better the great deal of order that appears to exist in the natural world we experience – much of which is there only because we put it there. They allow us to conceptualize cultural content as a number of general-purpose models, which are instantiated in line with the special purposes in daily life. They explain how the enormous amount of knowledge can be mastered, namely by storing only its prototypical parts, which are then actualized on demand and enriched with details. And they allow us to consider how people interpret new experiences because these models not only represent knowledge but also afford inferences to new situations.

Besides these achievements, three fields of research remain productive for theorizing in anthropology and for exchange across disciplinary boundaries.

Knowledge and Knowing

Most of what people know is not directly accessible because it is rather practical in character, incorporated in encounters, and encoded in the routines of social life (Giddens, 1984). When asked to describe how to ride a bicycle, one realizes that the traditional conception of *knowledge* – that which is known, as an abstract pool of information, declarative and verbalized – needs to be modified. *Knowing* how to do something in practice – being implicit and hidden, accessed primarily though performance – is at least as interesting for anthropological inquiry. For this reason, Borofsky (1994) suggested that we reorient our analysis and reverse the process, starting with knowing and then exploring how knowledge is constituted from it.

These insights have led to new trends, in both anthropology and the cognitive sciences more broadly. One has given rise to the parallel distributed processing models, also called connectionistic models or neuronal networks, developed by Rumelhart and McClelland (1986) and adopted for anthropological theorizing by Strauss and Quinn (1997). What intrigues anthropologists about this approach is that it allows modeling the functioning of patterns not "as loading in a set of instructions, but as gradually building up associative links among repeated or salient aspects of experience" (Strauss and Quinn, 1997, p. 50) or, in other words, as being dependent on our everyday lives, including the cultural phenomena.

A related trend in this vein is an increasing interest by anthropologists in how ways of knowing are embodied (Ingold, 2011), and this converges with the increasing interest by cognitive scientists in how cognitive concepts and processes may also be embodied (Barsalou, 2008). The underlying assumption is that information is memorized and represented in the same way in which it was originally encoded by the sensomotoric system, which provides a direct link to the environment (Gibbs, 2005). This assumption, backed up by neuroscientific findings, goes beyond previous ideas, in that cognition is no longer regarded as a collection of abstract representations stored solely in the brain, but as grounded in perception and behavior, and thus eventually embodied (De Vega et al., 2008; Fuchs, 2008; Klatzky et al., 2008).

Language and Cognition

The question of whether language shapes thought was dismissed in the wake of the cognitive revolution, but re-emerged some 20 years ago (Gumperz and Levinson, 1996) as one of the most promising fields for exchange between anthropology, linguistics, and other cognitive sciences. A prime example in this field is the research on spatial orientation and communication. While certainly belonging to the basic cognitive and linguistic equipment of all people around the world, systems of orientation differ across languages and cultures, and even apparently basic spatial categories such as 'left' and 'right' cannot be taken for granted (Levinson, 2003). Several languages that lack these terms use a geocentric system instead – based, for example, on the cardinal points – and not only in navigation, but also in everyday life (the glass is then not placed 'to the left of' the plate but, say, 'to the east'). These linguistic and cultural differences influence the perception of spatial relationships as well as their storage in memory (Wassmann and Dasen, 1998; Majid et al., 2004). Here, cognitive anthropology contradicts a school of thought for which the worldwide diversity of languages is only a cultural phenomenon and hence one of surface, and this gives rise to an ongoing dispute (Li and Gleitman, 2002 vs Levinson et al., 2002; and see Haun et al., 2011; Li et al., 2011). A medium position in this dispute is that although language may be taken as an important part of cultural transmission, it does not determine cognition (in the sense of a strong linguistic relativism) but is only one aspect of the overall ecocultural framework (Dasen and Mishra, 2010, 2013).

Universal or Cultural Variable?

Cognitive processes, such as perception, categorization, and memorization, are the foundations of knowledge acquisition and of the structure of its content. In principle, they are thought to be universal, albeit applied to particular contexts in different ways. Segall et al. (1990, p. 184), for instance, report cross-cultural differences in habitual strategies for classifying and problem solving, in cognitive styles, and in progression rates during development; but they consider them to be differences in performance rather than in competence.

Exploring under which circumstances and to what extent these differences occur remains one of the core tasks for the future (Henrich et al., 2010a,b) and one of those fields in cognitive science to which anthropology can – and should – contribute with its unique expertise (Bender and Beller, 2011b; Bender et al., 2012). Domains for which this is already under way include space and time (Bender et al., 2010; Haun et al., 2011; Núñez et al., 2012a); causality (Bender and Beller, 2011a); numerical cognition (Beller and Bender, 2008; Bender and Beller, 2012; Núñez et al., 2012b; Pica et al., 2004); biological and ecological reasoning (Atran and Medin, 2008; Bang et al., 2007; Medin and Atran, 1999; Medin et al., 2006); and religious concepts such as the notion

of an afterlife (Astuti et al., 2004; Whitehouse and McCauley, 2005; Astuti and Harris, 2008). This also includes an upsurge of interest in more complex topics that had been excluded from the cognitive sciences in their early phase (Gardner, 1985), and some of these issues are brought to the fore by anthropologists: the relation between emotion and cognition (Röttger-Rössler, 2004); the development of moral reasoning or theory of mind in specific cultural settings (Wassmann et al., 2013); and the phylogenetic evolution and ontogenetic development of complex phenomena such as religion and social cooperation (Henrich et al., 2010a,b).

More and more cognitive scientists, meanwhile, acknowledge the need to scrutinize universality rather than simply to postulate it. To further sensitize cognitive scientists to this endeavor and to make progress in this direction is a task for which no discipline is better suited than anthropology.

Cognitive Archaeology

Marc A Abramiuk, USA

This article is a revision of the previous edition article by D.S. Whitley, volume 3, pp. 2085–2089, © 2001, Elsevier Ltd.

Abstract

Cognitive archaeology, also called the archaeology of mind, is a burgeoning branch of archaeology that has as its focus of investigation the mind in the past. Cognitive archaeology makes use of several forms of evidence to infer past peoples' cognitive capabilities and mind frames (e.g., concepts and percepts), the most obvious being the material remains constituting the archaeological record. From these remains and their distributions, cognitive archaeologists attempt to make informed claims for understanding how people in the past thought and what they thought about. Cognitive archaeological inquiry is cross-disciplinary, such that in addition to relying on inferences made from archaeological data, cognitive archaeologists also depend on evidence that other disciplines, such as physical anthropology, cognitive anthropology, cognitive science, neuropsychology, linguistics, and philosophy, can bring to bear on the question of mind frames and mind functioning in the past. Despite the cross-disciplinary nature of cognitive archaeology, cognitive archaeologists are first and foremost archaeologists and, as such, maintain a predominant concern with what can be learned from material culture. For this reason, cognitive archaeologists have become mutually invested in the study of how humans interact with material culture, and the different ways the mind might be constituted through this engagement. Over the past decade, cognitive archaeologists have begun to form their own distinctive views regarding how the mind operates in relation to the material world, and this has contributed significantly to our general knowledge of the nature of the mind.

Definitions

Although the term 'cognitive archaeology' was used to refer to mind-related archaeological research as early as the 1970s (Flannery and Marcus, 1976: p. 374), it was not until the early 1980s that an agenda was articulated consisting of several questions with which cognitive archaeology was meant to concern itself (Renfrew, 1982: p. 2). One of these questions pertained to how archaeologists infer 'intelligent behavior' from material remains (Renfrew, 1982: p. 2), a concern that would formally lead to defining cognitive archaeology as "the study of past ways of thought as inferred from material remains" (Renfrew, 1994: p. 3). This definition was spawned to account for archaeologists working in the area of cognitive evolution (e.g., Wynn, 1979) as well as archaeologists who recognized the need to account for culturally specific belief systems when attempting to explain the archaeological record (e.g., Flannery and Marcus, 1976). The purpose of cognitive archaeology as envisioned by these archaeologists, it should be noted, was distinctive, albeit related to one of the main objectives that postprocessual archaeologists were pursuing contemporaneously, namely to uncover the 'meanings' or mind frames that were theorized to constitute the archaeological record (Hodder, 1982a,b). Where the approaches differed was on an epistemological level and, in particular, on the kinds of questions concerning the mind that were proposed to be illuminated through archaeological research. To highlight the difference, Colin Renfrew, for example, used the term cognitive-processual archaeology often in place of the term cognitive archaeology to delineate how he envisioned conducting mind-related archaeological research (Renfrew, 1994). In emphasizing the processual component, Renfrew was stating that cognitive archaeology was a scientific endeavor rather than a series of contextual and empathetic efforts, like those being explored by postprocessualists.

Today, cognitive archaeology may mean slightly different things to a cognitive archaeologist depending on his or her specialty. For example, it may mean the study of cognitive evolution, ancient belief systems, or experience and perception in the past. A recently published definition of cognitive archaeology that attempts to include these various foci, sees cognitive archaeology as "a subdiscipline of archaeology comprised of several practical approaches to studying the mind in the past" (Abramiuk, 2012: p. 15). This definition, in its generality, acknowledges the variety of mind frames and cognitive capabilities archaeologists examine and, consequently, the need for a number of investigative approaches; it also recognizes the need to consider other forms of inferential evidence (e.g., genetic and neuroscientific) to enter into the inquiry process in addition to archaeological data.

Philosophical Commitments

In the history of archaeology, inquisitiveness about past people's thoughts goes back to the beginnings of antiquarianism, but legitimate methods for pursuing this interest do not become apparent until the mid-twentieth century with the first speculative but grounded forays into understanding Upper Palaeolithic cave art (e.g., Breuil, 1952). With the exception of a few scholars who contended – or implied – that past human mind frames could be uncovered in the features and artifacts they studied (e.g., Leroi-Gourhan, 1964; Spaulding, 1960: p. 76), the 1960s and 1970s were dominated by the 'New Archeology' movement. The 'New Archeology,' more widely known later as functional-processual archaeology (processual archaeology), focused on *explaining* the archaeological record and utilized a logical empiricist methodology adopted from Carl Hempel (1962) to accomplish this objective. Processualism's commitment

to a hard-lined empiricist – if not positivistic – stance, however, would disallow inquiries about the mind in the past and the mind's role in archaeological explanation, cynically referring to such attempts as 'paleopsychology' (Binford, 1965: p. 204). As a result, it would not be until the mid-1970s and 1980s that mind-related studies in archaeology – beginning to be referred to as cognitive archaeology at this time – would begin in earnest.

The emergence of cognitive archaeology and its associated philosophical commitments can be fundamentally retraced to the same epistemological challenge processual archaeology faced early in its development, as it sought not merely to describe culture change evincible in the archaeological record, but to explain it. This challenge consequently was imparted to processual archaeology through its adoption of the covering law model found in logical empiricism. In processual archaeology, the covering law model (also known as the deductive-nomological model) was seen as a way of explaining patterns in the archaeological record deductively – that is, by virtue of expecting such patterns in light of general laws governing human behavior and certain observable initial conditions. The challenge in using the covering law model, however, lies in the fact that the model does not require that the observable initial conditions be connected in a *causally relevant* or substantive manner to the patterns in the archaeological record, and as such does not preclude alternative explanations for the archaeological patterns (Salmon, 2001: p. 235); this, of course, makes processual archaeological explanations difficult to logically falsify. Indeed, it implies that conditions that are unobservable or simply not considered by the processual archaeologist (e.g., the beliefs people had in the past) may also explain the archaeological patterns in question and, in fact, may explain the patterns more adequately. The realization that the explanatory model used in processual archaeology lacked sufficient scope effectively opened the door to mind-related archaeological research and, in turn, cognitive archaeology.

The rise of cognitive archaeology, however, would not have been secured were it not also for a divergence from the semantic position taken by processual archaeologists as it pertained to unobservable conditions. Processual archaeologists, in following the logical empiricists, treated unobservable conditions (e.g., cognitive states and beliefs) either in a nonliteral way (Binford, 1973: p. 227) or as meaningless because archaeologists were believed to be ill-equipped to delve into such conditions (Binford, 1965: pp. 204–205). As a result, processual archaeologists were inclined to focus on behavior, explaining cultural continuities and changes in the past as adaptations to external stimuli often taken to be environmental in origin.

In diverging from processual archaeologists, cognitive archaeologists take a semantic stance in which the value of considering unobservable phenomena is not denied. In cognitive archaeology, unobservable phenomena, such as cognitive capabilities and cultural beliefs, are treated explicitly as subjects of study or as factors in explaining observable patterns in the archaeological record. In other words, cognitive archaeologists assert that the mind is something to be taken literally and that it furthermore can be reconstructed or understood through material remains.

Where cognitive archaeologists may semantically differ is in how they interpret the relationship between mind and material, which stems from different ontological commitments. Notable ontologies that have gained favor in cognitive archaeology are those that merge mind and material; and these have, in turn, contributed to the varying degrees in which cognitive archaeologists literally construe the mind as contiguous with the brain, body, and material world. Cognitive archaeologists, therefore, may take slightly different semantic lines when speaking of the mind in its relation to brain, body, and material world that can range from realist to phenomenological (*see* Archaeology, Theory in).

Changes in the Focus of Mind-Related Studies in Archaeology Over Time

Beginning in the 1970s and continuing through the 1980s, as mind-related studies in archaeology were seeping into archaeological research, two trends can be seen to have emerged. The first trend included archaeologists who retained a processually derived systemic view of ancient societies, and who considered the relevance of the mind, but mainly as a factor to help explain culture change evidenced in the archaeological record. The second trend included archaeologists who were significantly more radical. These archaeologists adopted linguistic and psychological models of the mind, which encouraged treating the mind as the subject of study in archaeological investigation.

The first trend in mind-related archaeological research remained committed to the goal of providing explanations for past phenomena, just as it always had been in processual archaeology. The difference between the two approaches, however, lay in the nature of the *explanans* – a term derived from Hempel and Oppenheim (1948) and adopted by some archaeologists to describe the factors used in explaining a particular archaeological phenomenon. In mind-related archaeological studies, an ideational-themed *explanans* was simply substituted for an environmental- or technological-themed *explanans*, such as those popularly employed in processual archaeology. The research objective continued to emphasize explaining cultural continuity and change in the archaeological record; what changed were the factors used to do the explaining. Instead of resorting to material factors, archaeologists began to consider ideational alternatives such as past beliefs. These ideational factors were typically revealed through a process of ethnographic comparison and then assessed against the archaeological evidence. Flannery and Marcus (1976) exemplify this trend in mind-related archaeological research by explaining Zapotec agricultural practices, village life, and burial patterns in Formative Oaxaca by factoring in proposed religious beliefs recorded in ethnohistoric sources. In another example of this trend, Hall (1976) explains how the belief in the ability to control for the movement of spirits – a belief that is widely described in ethnographic accounts of certain contemporary Native American peoples – might have been the impetus for the construction of ditches and earthworks during the Eastern Woodland period.

The second trend in mind-related archaeological studies made extensive use of linguistic and psychological theories to understand what and how people thought in the past. It involved reconstructing mind frames and thought processes evidenced in the archaeological remains; however, rather than solely being directed by ethnographic comparison, it was guided by theories concerning the cross-cultural nature and development of the human mind. For this reason, the structuralist notion of a universal, underlying set of operations for relating concepts in the mind became a common theoretical platform for archaeologists seeking to piece together thoughts from the past. McGhee (1977), for example, examined the way in which the Thule of Arctic Canada selected tool-making raw materials by proposing that their selections were motivated by binary oppositional relations, which he proceeded to reconstruct. In this second research trend, inferences regarding what and how people were thinking often became the ends of research, and the archaeological remains, the means for inferring the mind frames and thought processes. Some of the earliest research regarding reconstructing thought processes was conducted by Thomas Wynn. Inspired by Piagetian psychological theory, Wynn (1979) was able to gain valuable insight into the cognitive capabilities of Acheulean toolmakers through an extensive analysis of Acheulean tools.

Both trends in mind-related archaeological research would persist into the next decade and beyond; however, they would largely be caught up in a contemporaneous movement pervading archaeological theory – the objective of which was to uncover social life in the past. Political power, social relations and divisions, among other social phenomena, became aspects of social life that archaeologists attempted to uncover from the archaeological record, and this facilitated mind-related archaeological studies on several levels. For instance, the related notions of ideology and consciousness – notions critical for understanding power and social divisions – naturally implied a need to understand the mind frames of the people being studied (Hodder, 1982a), as well as those of the archaeologists (see Leone, 1982: p. 751). Delving into the social aspects of ancient life, specifically through a Marxist lens, was nothing new in archaeology as it had been proponed by Gordon Childe and others decades before; however, social theory's marriage to structuralism to uncover the social mind through artifact assemblages was distinctive. Hodder (1982b), for instance, showed through successive ceramic sequences that aspects of a Dutch Neolithic ideology, serving to legitimize social relations and contradictions, could be identified through a structural analysis of pot decorations. Such studies that incorporated social theory as well as explored mind frames soon came under the umbrella of postprocessual archaeology.

Similarly motivated but alternative attempts at gleaning insight into the social circumstances of people in the past were proposed by Colin Renfrew. In contrast to advocating theory-driven understandings of social life, emphasis was placed on what empirically driven inferences – largely through spatial patterning – could succinctly say about sociality in ancient times. For Renfrew (1982), the acknowledgment that social life in the past could be teased from the archaeological record was encouraging and helped pave the way for accepting that cognitive aspects of people in the past also could be investigated. For the first time an explicit agenda for cognitive archaeology was put in place in which systems of thought (e.g., measurement, planning, and religion) could and would be examined only insofar as these systems were relevant for the functioning of ancient society and clearly expressed in material remains (Renfrew, 1982: p. 11). By the end of the 1980s, it was evident that postprocessualists were concerned with instances of thought and processualists were concerned with systems of thought. In the United Kingdom, these different ways of looking at cognition would become gradually more divergent in the following decade. In other parts of the world, such as South Africa, where significant research on cognitive evolution and the origins of art was being conducted (e.g., Lewis-Williams and Dowson, 1988), cognitive archaeologists were less affected by the polarization.

In the 1990s, a statement was formally issued that would distinguish two camps with distinct aims and ways for studying the mind in the past (Renfrew, 1994). The postprocessual camp would have as one of its purposes the uncovering of meanings, namely *what* people thought in the past. Its plan for elucidating these meanings or mind frames would rely on structural (Hodder, 1982a,b), historical (Hodder, 1987), phenomenological (Thomas, 1996; Tilley, 1994), and other interpretive approaches. The cognitive-processual camp, on the other hand, would strive to understand *how* people thought in the past inclusive of their cognitive capabilities and symbolic systems (Renfrew, 1994). One area of research that lay squarely within the mission statement of cognitive-processualists was cognitive evolution, a topic that saw a surge of interest and gained serious attention from specialists in the cognitive sciences (e.g., Donald, 1991). Cognitive-processual archaeology would be conducted from a scientific realist position, and rely on a method of logical inference by which systems of thought would be guardedly arrived at through supporting evidence derived from cultural remains. Eventually the term 'cognitive archaeology' would come to be associated with the cognitive-processual camp's aim and approach, while the study of the mind in the postprocessual school would increasingly come under the sway of archaeological phenomenology (Gosden, 1994; Tilley, 1994; Thomas, 1996) and material culture theory (Miller, 1987; Tilley, 1999). Although, the cognitive-processual and postprocessual schools of thought continued along separate paths through the dawn of the new millennium, certain convergent viewpoints became noticeable. The similarity of viewpoints can largely be attributed to a major undercurrent in archaeology that stressed materiality.

Just as the sociality movement helped give impetus to studying the mind in archaeology in the 1980s, so too did the materiality movement help propel cognitive archaeology in the 2000s. The kernels of the materiality movement could be traced back to Hodder's (1982a,b) work on the active role of material culture in society; however, the role of material culture in social interactions and its relation to the mind was fostered extensively in the late 1980s and 1990s in the postprocessual work of Daniel Miller, Christopher Gosden, and Christopher Tilley. By the early 2000s, the notion of materiality was ripe for study by cognitive archaeologists as well as by the

postprocessual archaeologists who helped bring materiality to the forefront of archaeological investigation. Whereas postprocessual archaeologists tended to focus on the meaning of material culture in and for a society, cognitive archaeologists preferred to address the broader, generalizable ramifications of material culture's role in the functioning of the mind.

In cognitive archaeology, one of the fruits of labor that resulted from exploring materiality was the formulation of material engagement theory (MET). First propounded by Colin Renfrew (2001, 2007) and elaborated upon by Lambros Malafouris (2004, 2013), MET goes beyond the statement that advocates of materiality make regarding the primacy (or at least equivalency) of material culture in its relationship with the mind. MET makes the claim that the mind and the material that comprise us, our surroundings, and our actions within these surroundings are ontologically indivisible; as such, it views the mind as embodied, extended, and enacted. MET does not make it a priority to struggle to uncover the meanings or instances of thought *behind* material culture, particularly, since thought is seen as inseparable from material culture. Rather, the aim of MET is to understand in a holistic manner how the human mind works through material things and action and, in so doing, aids in its development.

Current Thinking about the Field

Historically, archaeologists have tended to gravitate toward one approach or another for understanding the mind in the past – often out of theoretical inclination and without due attention to the approach's substantiation. Recent research, however, has placed six such approaches on more solid ground by detailing their empirical and logical foundations (Abramiuk, 2012). This research finds that these approaches can be utilized productively depending on the precise context and objective of the cognitive archaeological inquiry. These six approaches, which can be used alone or in certain cases jointly, are briefly described below.

The General Comparative Approach

Early attempts at utilizing what could be regarded as a general comparative approach in mind-related archaeological studies date to the dawn of the twentieth century (e.g., Reinach, 1903). However, it has only been in the past several decades, particularly through the work of anthropologists and archaeologists at the University of Witwatersrand, that the general comparative approach has been developed for the purposes of cognitive archaeological research (e.g., Lewis-Williams and Dowson, 1988). Grounded in cognitive scientific research and applied strategically to illuminating specific mind frames, the general comparative approach has proven to be constructive for understanding the motivations for and significance of early parietal art in several parts of the world, from the Upper Palaeolithic cave art of the Franco-Cantabrian region (Lewis-Williams, 2002) to the late prehistoric rock art in far western North America (Whitley, 1992).

The objective of the general comparative approach, as it is used in cognitive archaeology, is to ascertain the mind frames of people in the past by the way of ethnographic comparison. This is accomplished by guardedly projecting beliefs and perceptions of a well-documented group of people onto a target group – the people in the past whose material remains are the subject of inquiry by the archaeologist. The procedure first entails identifying a relevant societal analog to the early society being investigated by the archaeologist, and then drawing inferences from this analog. General comparative inference is supported by cognitive scientific evidence for the universality and, hence, translatability across cultures of certain properties of the human mind in similarly situated social contexts. For this approach to work, however, it is of course paramount to demonstrate that the social environments of the two peoples being compared share conditions that have understood cognitive implications that can aid in the reconstruction of mind frames.

The Direct Historical Approach

The direct historical approach has been used as a way of reconstructing ancient practices from modern ones since at least the early twentieth century. However, its formal recognition as a means of inferring ancient mind frames can be attributed to work of Marcus and Flannery (1994), who utilize the approach for the sole purpose of gleaning insight into ancient Zapotec religious beliefs during the Formative period.

The direct historical approach is related to the general comparative approach in that it seeks to reconstruct mind frames through ethnographic comparison with a well-documented societal analog. However, instead of selecting the analog to be an arbitrary group that shares social organizational attributes to the group in the past being investigated, the direct historical approach bases its inferences on an analog that is culturally – if not, genealogically – related to the target group. The direct historical approach gains insight into the concepts (e.g., religious beliefs) of past peoples then by retracing the concepts that would have been passed down directly – generationally – to the cultural analog. Cognitive anthropological research confirms the saliency of concepts reproduced intraculturally, and therefore supports the long-term continuity or preservation of culturally bounded concepts. Accordingly, culturally bounded concepts can be envisaged as notions from the past that have been passed down through time while resisting significant alterations to their original form.

The Associative Approach

Although, the associative approach has been used in archaeology since the early nineteenth century to relatively date cultural remains and elucidate ancient practices, the implication that it could be utilized to infer mind frames from archaeological assemblages is more recent (e.g., Spaulding, 1960: p. 76). The associative approach is extremely useful in cases where all that is known about the people in the past being studied is that which can be gleaned from the archaeological data. In this way, the associative approach differs substantially from the ethnographic comparative approaches discussed above.

The associative approach takes a drastically different track than the general comparative approach in particular. Rather

than imparting mind frames – often in the form of intact belief systems – from one society onto another, attempts are made to reconstruct concepts through an understanding of how concepts universally relate to one another in the mind.

The associative approach commences by observing and analyzing the cultural remains left behind. Through the contextual analysis of the remains, the associative approach proceeds to identify clearly evincible concepts associated with the remains and the categorical relations between them so that larger semantic conceptual constructs known as categories can be reconstructed from the past. Whereas semantic concepts, such as categories and the concepts, that make them up are often culturally specific, the fundamental manner in which categories form is cross-cultural, and it is this cognitive scientifically substantiated insight that enables the archaeologist to reconstruct them directly from the archaeological record. Kim (1994) implicitly exemplifies this procedure as he principally utilizes an associative approach to argue that pigs served as prestige items in the minds of certain Neolithic peoples in China.

The Structural Archaeological Approach

Advocated as early as the mid-twentieth century by Leroi-Gourhan (1964), the structural archaeological approach, like the general comparative approach, was adopted to uncover the meaning behind Upper Palaeolithic cave art. It maintains many of the same features as the associative approach, particularly the capacity to infer mind frames directly from the archaeological record, and it remains a useful approach where oppositionally related concepts can be detected.

The structural archaeological approach is similar to the associative approach in that it seeks to reconstruct concepts from archaeological data; however, the structural archaeological approach's distinct emphasis is on reconstructing *composites* of concepts known as opposite analogies. The procedure follows a similar sequence of steps as the associative approach, beginning with the observation of cultural remains and a subsequent contextual analysis for the concepts associated with the remains and their relations. What is different in the structural archaeological approach, however, is that oppositionally related concepts – rather than categorically related concepts – are sought among archaeological data for analytical reconstruction. An example of this can be seen in McGhee's (1977) study of the Thule in which he identifies and associates concepts attached to male and female cultural remains. He then uses the cross-culturally recognized oppositional concepts 'male' and 'female' to form the backbone for piecing together all other concepts associated with the cultural remains. Whereas the meaning of these latter concepts may be culturally specific and therefore tentatively unknown to the archaeologist, how these concepts relate has a known cross-cultural aspect since they are connected through the male–female oppositional relation. Cognitive scientific research supports the ability to analytically reassemble oppositionally related concepts (i.e., opposite analogies), since core stages in the analogical reasoning process responsible for the formation of opposite analogies – and the steps with which cognitive archaeologists are concerned as they pertain to reconstructing opposite analogies – are cross-cultural.

The Conditional Approach

Although the term 'conditional approach' was never actually used in mind-related archaeological research, it was Colin Renfrew (1982, 1994) who first laid out an agenda advocating the use of deductive reasoning to infer cognitive capabilities as logical consequences of the presence or absence of certain cultural remains. The term 'conditional approach' is used to refer to this reasoning strategy and, in particular, how arguments are often expressed using this approach – namely in the form of conditional statements (Abramiuk, 2012: pp. 141–152). It continues to be one of the most intuitive as well as adaptable approaches available to the cognitive archaeologist. The conditional approach is mainly concerned with ascertaining *how* people thought in the past, rather than what they thought about. As such, it stands in stark contrast to the other approaches discussed.

Rather than being used to reconstruct mind frames, the conditional approach is commonly utilized to postulate the existence of certain cognitive capabilities, whether they are general memory systems or more particular systems of thought such as measurement and planning. The conditional approach undertakes this endeavor by inferring the cognitive capabilities that would have been needed to produce the behavior responsible for the cultural products left behind. More specifically, the conditional approach sets up logical arguments in a conditional manner, such that some behavior or remain is *contingent* on a certain cognitive capability. Establishing an argument this way, allows the archaeologist to present conclusions about mental functioning in the past in a manner that can be analyzed objectively and systematically verified or rebutted. Because the conditional approach is logic-based, rather than empiric-based, and because it is concerned with thought processes rather than instances of thought, it constitutes a substrate-independent approach. As such, the conditional approach can be used to infer cognitive capabilities of virtually any species, and this makes it particularly valuable in cognitive evolutionary studies (e.g., Wynn, 1979; Mithen, 1996).

The Materiality Approach

Despite having earlier roots (e.g., Barrett, 1994; Miller, 1987; Tilley, 1994, 1999), the materiality approach formally entered cognitive archaeology through the work presented in an edited volume entitled *Rethinking Materiality: The Engagement of the Mind with the Material World* (DeMarrais et al., 2004). The term, 'materiality approach' refers to a spectrum of cognitive archaeological inquiries, each comprised of nuanced differences, but all emphasizing the material world and its primacy over or equivalency with the mind. The materiality approach constitutes one of the more recent analytical attempts at understanding how the human mind functioned in the past (as well as functions in the present). It achieves this understanding by concerning itself with how humans in their natural settings engaged with material things and how these interactions shaped their minds.

Although the materiality approach, like the conditional approach, is concerned with how people thought in the past, it achieves this understanding through the dynamics of perception–action which can, in turn, facilitate the recovery of certain percepts (Abramiuk, 2012: pp. 105–112). More specifically, the materiality approach analytically simulates the process by which people in the past 'thought' as they interacted with their surroundings by focusing on the ways in which people universally 'perceive' things through engagement. Provided the surroundings in question have not changed significantly from ancient times, some of people's accompanying percepts of material forms in the past can become relatable to an archaeologist in the present. A similar line of reasoning can be used to derive meanings that would have been afforded by these ancient human–object interactions (e.g., Knappett, 2005: pp. 133–166). Much of the extradisciplinary support for the materiality approach and how it can facilitate the recovery of certain percepts and meanings can be found in the cognitive anthropological and ecological psychological research on direct perception (e.g., Warren, 1984).

A variant of the materiality approach that has come to the forefront of cognitive archaeological research in recent years is MET. MET's calling card is its stance on the unity of mind and material, and it concerns itself less with attempting to elucidate mind frames and more with tracing thought 'through' the object and/or action with that object. More generally, MET is concerned with understanding how the mind works as a totality, inclusive of the body and the material world. Because of MET's advocacy of an embodied, extended view of the mind, MET finds much support in the recent literature on the philosophy of mind (e.g., Clark, 1997) and is gaining some empirical backing in neuroscientific studies (see below).

Emerging Directions in Theory, Practice, and Research

Cognitive archaeology is a rapidly expanding field with many advancements being made in both theory and practice. At present, few cognitive archaeologists would disagree with the statement that despite advancements in the field, the mind in the past – let alone, the mind in the present – remains a complex and incompletely understood phenomenon. Where specialists involved in the development of cognitive archaeological theory and practice differ, is with regard to the lines of inquiry they pursue in contributing to the field. For some cognitive archaeologists, the starting point for such an inquiry is a metaphysical position regarding the nature of the mind, and for others it is an epistemological concern for the utility of a particular cognitive archaeological approach. The archaeologist who begins with a metaphysical stance concentrates on developing an approach for studying the mind in the past based on his/her understanding of the nature of mind. The epistemologically concerned cognitive archaeologist works in reverse by initially focusing on the approach utilized, and then analyzes the validity and scope of the approach to determine its basis. Both ways of contributing to cognitive archaeology are apparent in the literature to date, and both ways add to our overall knowledge of the subject, which consequently helps to advance research. Among the research areas emerging as the result of taking the former (metaphysical) line of inquiry and latter (epistemological) line of inquiry are neuroarchaeology and foundations, respectively.

The development of neuroarchaeology in recent years can partly be seen as a consequence of a recently introduced perspective regarding the nature of the mind, which sees the mind as embodied and extended. What this view has accomplished for cognitive archaeology, and which is articulated in MET, is to link archaeology with neuroscience, thereby bridging the gap between culture and the brain. This marriage between archaeology and neuroscience, referred to as neuroarchaeology, shows much promise in advancing cognitive studies since both archaeology and neuroscience have the ability to examine the relationship between brain and culture from distinct vantage points. The field of archaeology studies human lives over significant time frames through material remains. This makes archaeology a field particularly suited to studying a mind that is inseparable from (material) culture and engaged in specific activities or practices over the long term. Neuroscience, on the other hand, is equipped to study the immediate and short-term effects of engagement with culture on the brain through neuroimaging and other monitoring techniques (Stout and Chaminade, 2007). Provided researchers avoid embracing a crude neurocentric position, the subfield of cognitive archaeology known as neuroarchaeology has the potential to provide keen insight into the study of cognitive evolution and, in particular, the notion of brain plasticity as it relates to culture and the material world (Malafouris, 2013: pp. 168–169, 229–330).

A different emerging research trend is foundational studies in cognitive archaeology. Like many disciplines, cognitive archaeology has undergone an epistemological dilemma that is natural for a field that has been fueled mainly by the need for a variety of approaches to study the mind, often at the expense of establishing solid bases for their utilization. Approaches to studying the mind in the past, since the emergence of mind-related studies in archaeology, often involved assumptions regarding how the mind works without substantial cross-checking of empirical research in related disciplines. Foundational research in cognitive archaeology consequently focuses on the epistemological issues that have emerged in cognitive archaeology. Instead of devising new approaches, foundational research synthesizes and analyzes the approaches that have been utilized throughout the last several decades, determines their limitations, and tries to situate them more firmly on logical and empirical grounds. Abramiuk (2012) has taken one of the first steps toward such a foundational inquiry, and others (e.g., Garofoli and Haidle, 2013) similarly have been quick to realize that epistemological issues need to be considered before any knowledge claims are to be made in cognitive archaeology.

Abstract

Cognitive behavioral therapy (CBT) is a form of psychotherapy focused on the 'here and now,' which is based on the assumed interaction between our emotions, cognitions (mental events including thoughts, memories, images, etc.), and our behaviors. CBT aims to promote change by helping an individual to understand and then alter the way they think, and/or the things they do, leading to indirect changes in the way they feel.

History and Development

In the early twentieth century, attempts to understand the human mind were based on introspective studies of consciousness. Behaviorism evolved with the ambition of creating an objective science with which to study observable behavior (i.e., Watson, 1913; Skinner, 1974). Based on the principles of learning theory, behaviorist explanations of human behavior asserted that behavior is more or less likely in a particular context, due to prior learning (or conditioning) about the consequences that follow that behavior.

In the 1970s – a time of computer modeling and study of cognition – behaviorism, with its absence of an account of conscious mental processes, was felt by some to be limited, overly descriptive, and deterministic. Beck (1976), originally a psychoanalyst, built on the behavioral assumption that an individual's history and experiences will guide their behavior by suggesting a means of how this influence may be transferred. Beck's cognitive theory of emotional disorders (Beck et al., 1979) describes how learned principles are stored in cognitive structures or 'schemas.' Emotional distress is, therefore, caused not directly by environmental contingencies rather by experiences mediated through distorted or unhelpful cognitions.

In line with this theory, Beck developed cognitive therapy, based on the premise that, given the guidance to do so, an individual could be able to identify within consciousness their maladaptive reactions, and use logical problem-solving skills to correct these themselves. Beck's cognitive theory gained prominence through experimental validation of its principles, and through positive evaluation of the resulting therapy (e.g., DeRubeis et al., 2005).

Over the last 20 years, a range of third-wave cognitive and behavioral therapies have developed in a continuing effort to further hone the cognitive theory by identifying the active components and mechanisms and to improve treatment for emotional difficulties. For example, mindfulness-based cognitive therapy (MBCT, Teasdale et al., 2000) was developed in an attempt to combine the short-term pragmatic and financial benefits of pharmacotherapy for treatment of depression with the relapse-protective benefits of cognitive therapy. MBCT assumes that cognitive therapy achieves its effects through helping an individual to alter their extreme, absolutist, dichotomous thinking style, thus changing an individual's relationship with their thoughts and modifying the reciprocal relationship between negative thoughts on low mood. Third-wave theories may vary in philosophical and pragmatic positions; however, they generally focus on the function, rather than the form of cognitions in understanding their role in distress. For example, dialectical behavior therapy (Linehan, 1993) combines CBT with skills training groups and team consultations and has been developed for the treatment of borderline personality disorder. Acceptance and commitment therapy (Hayes and Smith, 2005) uses acceptance and mindfulness strategies to encourage an individual to commit to engagement in valued activities.

Cognitive Behavioral Theory

Beck's cognitive theory of depression (Beck et al., 1979) describes how, through early experiences, people develop beliefs about themselves, the world, and the future. This information is stored as stable, global, core beliefs, not immediately accessible to conscious reflection. Core beliefs may be activated by environmental triggers, such as a situation that is relevant to, or consistent with its content. This leads to activation of conditional rules or 'dysfunctional assumptions' – strongly held personal rules, containing information about how the individual or environment should be in order to satisfy the core belief. Phrased as absolute demands, dysfunctional assumptions are often preverbal, excessive, and unreasonable. Active dysfunctional assumptions then interact with the environment to generate situation-specific statements known as negative automatic thoughts, which are accessible to awareness and lead to low mood and to the symptoms of depression including affective, cognitive, behavioral, and motivational responses.

Although early experiences are considered particularly important in the formation of core beliefs, through our lives we constantly interact with our environments, thus generating new information to update and correct them. However, certain cognitive processes may mean that unhelpful information persists despite new contradictory information. For example, individuals with depression show an increase in cognitive processes, such as mood-congruent thoughts or selective

attention, which manipulate interpretations of events, making it more likely that new information will be consistent with existing schemas.

Since the introduction of Beck's theory, specific cognitive accounts or models have been developed to explain emotional difficulties in other areas. These models are based on clinical observations, formed into hypotheses and tested through experimental methods. The overriding commonality between models is the assumption that distress is the result of an unhelpful interpretation of an environmental or internal trigger. The nature of this interpretation will determine the emotional response. Those characterized by overestimation of threat are likely to lead to anxious responses, interpretations of loss lead to a sad or depressed emotional response, whereas interpretations connected to injustice may lead to angry responses. These interpretations are then unwittingly and unfortunately maintained through a combination of cognitive, behavioral, affective, and interpersonal responses, the relative contribution of which are differentially emphasized across various different psychological problems. For example, an individual presenting with a phobia of dogs may experience their distress as a result of their interpretation that "all dogs are dangerous and will bite me," which may be triggered every time that a dog is present in their immediate environment. This interpretation of threat may then be maintained through an avoidance of all dogs (thus precluding any opportunity for disconfirmation of this anxious prediction), and hypervigilance and cognitive biases around dog-threat related stimuli (therefore making it more likely that any barking in the area will be noticed and interpreted as a sign that a dog is out of control).

Cognitive Behavioral Therapy

Cognitive behavioral therapy (CBT) is delivered through a collaborative, empathic, nonjudgmental therapeutic relationship between therapist and client. CBT varies in duration and delivery, according to the target difficulty and therapeutic setting, however generally involves between 5 and 20 weekly sessions, lasting between 30 and 60 min. CBT is a focused psychotherapy – directed toward explicit meaningful targets identified by the client. CBT sessions themselves are also focused, making use of an 'agenda' to agree on shared goals for a session and ensure that adequate attention is allowed for these. Outcome-driven CBT involves regular evaluation toward its therapeutic targets, which may include the use of standardized or idiosyncratic measures.

CBT generally begins with an individualized assessment of current and historical factors, which may be contributing to the development and maintenance of the identified difficulty. From this assessment, a formulation is developed and shared. The aim of this formulation is to understand and explain the factors that may be influential in the focal difficulty, and based on this, to provide a plan for intervention. This formulation may then be updated and developed throughout the therapeutic intervention, as additional information is gathered.

Based on the formulation, intervention strategies will be used to support the individual to make changes. As such, a formulation, which indicates that an unhelpful interpretation is influential in leading to distress, may lead to strategies designed to update this interpretation with a more functional alternative. A formulation indicating that continued avoidance of a feared situation may be involved in maintaining a fear through lack of opportunity to disconfirm this appraisal would be likely to lead to an intervention that includes gradually and collaboratively eliminating the avoidance behavior to allow the client to become accustomed to the feared stimulus.

Strategies used within CBT are intended to facilitate the client to arrive at more helpful and functionally adaptive conclusions. Rather than reaching this change through teaching or offering insight, the therapist uses method such as 'guided discovery' and 'Socratic questioning' to draw information from the client themselves. Regular feedback is used to increase the shared understanding, promote insight, and focus on therapeutic issues. Within CBT, clients are encouraged to use discussion and education to seek further information with which to update their unhelpful beliefs. An intervention is also likely to include encouraging the client to behave in new ways or to conduct 'behavioral experiments,' in order to explore the consequences of alternative actions and make sense of these within their emerging framework. Other CBT techniques may include the use of role plays and diaries. Central to the aforementioned aim of supporting the client to identify and correct their own unhelpful reactions is the use of 'homework.' Clients are encouraged to develop and carry out between-session tasks to continue and expand their therapeutic change and increase the generalization of any within-session changes.

Applications

The majority of evidence around the effectiveness of CBT has been gathered through trials of treatment efficacy in different therapeutic areas. There is a strong evidence base for the use of CBT in the treatment of depressive disorders; CBT is equally effective to antidepressant medication, but with more enduring effects (e.g., Paykel et al., 1999). CBT is also the psychological treatment of choice for anxiety disorders (Butler et al., 2006) including social anxiety, panic disorder, obsessive-compulsive disorder, post-traumatic stress disorder, and generalized anxiety disorder. CBT is recommended in the treatment of eating disorders such as bulimia nervosa (Agras et al., 2000) and in the treatment of chronic fatigue (Malouff et al., 2008).

More recently, the evidence base has grown for the effectiveness of CBT in more severe and enduring mental health difficulties including treatment of schizophrenia (Tarrier and Wykes, 2004) with some benefit observed using CBT in the treatment of bipolar disorder (Scott et al., 2006) and in the treatment of personality disorders (e.g., Davidson et al., 2006).

As a time-limited, evidence-based, and focused therapy, CBT has been recommended extensively for use within the UK National Health Service. Recent initiatives designed to increase dissemination of CBT have led to the implementation of 'Improving Access to Psychological Therapies' services, designed to provide short-term outcome-driven psychological therapy to large numbers of clients within a primary care setting (Clark, 2011). This initiative has since been expanded in order to increase provision of these therapies for other groups including children and young people, and those with severe and enduring mental health difficulties. As such, emphasis has

been placed on development of more brief and focused interventions.

CBT is traditionally carried out by mental health professionals (e.g., nurses, psychologists, psychiatrists, etc.) with specific training in providing CBT. More specific packages and individual CBT skills can be used by practitioners without specialist training. The majority of outcome research into CBT has used individual therapy; however, CBT has also been applied in group formats (Tucker and Oei, 2007). It has been shown to lead to effective reduction of symptoms in a computer-delivered format (e.g., Hayward et al., 2007) and delivered through the Internet (Kiropoulos et al., 2007).

Criticisms of Cognitive Behavioral Therapy

In common with many psychotherapies and treatments, CBT is not suitable for everyone. The structured, present-focused stance of CBT may be uncomfortable for individuals who are unable to identify a focal difficulty, or who are interested mainly in gaining greater insight into their experiences. Furthermore, the collaborative attitude means that clients are required to undertake much of the responsibility and effort involved in making changes. There have also been questions about its cultural applicability, although, with adaptation, it can be successful (Rathod et al., 2013). This change necessarily involves moving outside of one's comfort zone, and as such is likely to be difficult for those with difficulties around low motivation or high avoidance.

Cognitive Control (Executive Function): Role of Prefrontal Cortex

Abstract

Cognitive control is the ability to direct mental function and behavior in accord with internally represented intentions or goals. This ability is fundamental to all higher cognitive faculties, such as language, reasoning, problem solving, and social behavior. While this ability no doubt relies on interactions between many areas of the brain, neuropsychological, neurophysiological, neuroimaging, and neural network modeling studies all indicate strongly that the prefrontal cortex plays a critical role in cognitive control. This article reviews these findings briefly, and suggests that the prefrontal cortex executes control by guiding the flow of neural activity along pathways in other parts of the brain responsible for performing an intended task.

Control refers to the ability to direct mental function and behavior in accord with an internally represented set of intentions. This is manifest in higher cognitive function in many forms: the ability to direct attention to a specific stimulus within a large array of other competing, and perhaps more salient stimuli (e.g., finding the face you are looking for within a crowd), maintaining a new and important piece of information in mind against distraction (e.g., remembering a telephone number you just got from the directory assistance until you dial the same, while in a phone booth at a noisy airport terminal), overcoming a compelling but undesirable behavior (e.g., suppressing the urge to scratch a mosquito bite) or pursuing a complex but unfamiliar behavior (e.g., playing a new piano piece) and, perhaps most importantly, the ability to respond flexibly and productively in novel circumstances (e.g., mentally explore the consequences of a complex sequence of moves in a game of chess).

The distinction between controlled and automatic processing is one of the central concepts within modern cognitive psychology. Controlled processing is considered to be effortful, and to rely on a limited capacity system, while automatic processing is assumed to occur independently of this system (Posner and Snyder, 1975; Shiffrin and Schneider, 1977). This concurs with common experiences, such as the ability to carry on a conversation while driving a car (an automatic process) but not while conducting multidigit arithmetic in one's head (a process that relies on control). Many contemporary theories posit that there is actually a continuum between controlled and automatic processing (for a review, see Cohen et al., 1990). Nevertheless, virtually all theorists acknowledge the need for some mechanism, or set of mechanisms, responsible for the coordination of processing in a flexible fashion – particularly in novel or demanding tasks. This idea figures centrally in Baddeley's classic theory of working memory (Baddeley, 1986), which postulates two critical components: a storage component responsible for the active maintenance of information in a short-term store, and an executive control component responsible for the manipulation and coordinated use of this information. For example, in a multidigit multiplication problem, the storage component maintains the intermediate products while the executive carries out the arithmetic operations.

The postulation of a central executive closely paralleled theorizing regarding the nature of frontal lobe function (for a review, see Shallice, 1982), based on the clinical observation that patients with frontal lesions exhibit a 'dysexecutive syndrome.' The frontal lobes are the areas of the brain most highly expanded in humans relative to other species (see Figure 1). Damage to this area is associated with impairments in characteristically human cognitive functions that are directly

Figure 1 Relative size of prefrontal cortex (gray region) in five species. http://www.psychol.ucl.ac.uk/kate.jeffery/c567/lecture13_frontal/overheads/img003.jpg.

dependent upon control (such as planning or the ability to respond adaptively in novel circumstances), and disturbances of this structure have been implicated consistently in neuropsychiatric diseases such as schizophrenia that also appear to be uniquely human. Indeed, the earliest neurologists, neuroscientists, and neuropsychologists recognized the importance of the frontal lobes in the control of behavior. Perhaps this observation was made most dramatically in the classic case of Phineas Gage, the unfortunate railroad foreman who suffered damage to his prefrontal cortex (PFC) when a 1½″-diameter rod penetrated his skull in a construction accident. Originally someone who was considered to be thoughtful, responsible, and of sound judgment, following the accident was described as "capricious…and unable to settle on any of the plans he devised for future action" (Harlow, 1848). Such changes have been observed repeatedly in patients with damage to the frontal cortex (for a review, see Stuss and Benson, 1986). Furthermore, patients with frontal damage perform poorly in tasks that require even the simplest forms of cognitive control, such as the Wisconsin Card Sorting Task (WCST) (Milner, 1964), and, most recently, brain imaging studies consistently have revealed increased activity of the PFC while subjects are performing tasks that demand cognitive control (for a review, see Miller and Cohen, 2001). Although this accumulation of findings has led most investigators to assume that the PFC plays a critical role in cognitive control, they have provided little insight into the specific contribution that it makes, or the mechanisms by which it operates. However, more detailed neurobiological studies have begun to shed light on this question.

Using single unit recording techniques, Fuster and Alexander (1971) and Niki (1974) reported the remarkable finding that some neurons in the PFC continue to fire during the delay between a stimulus and a contingent response, even after the stimulus has disappeared. Goldman-Rakic and her colleagues followed up on this finding and, in a series of elegant studies, demonstrated that the firing of such neurons was stimulus selective and was critical for performance in delayed-response tasks (Goldman-Rakic, 1990).

These findings strongly implicate neuronal activity in PFC as the site of temporary storage of information in working memory. Recent neuroimaging studies of humans have provided strong convergent support for this idea, demonstrating sustained activity in PFC during the performance of simple working memory tasks (for a review, see Smith and Jonides, 1999). However, this discovery seemed to pose an interesting puzzle. Most of the neuropsychological data suggested that the PFC housed the central executive which, at least within Baddeley's influential theory of working memory, was clearly distinguished from the storage component thought by most to be housed primarily in more posterior structures. Computational models of cognitive control have offered a different perspective on this problem that may reconcile the role of the PFC in control and storage.

Computational Models

Shallice (1982) presented the first account of the role of PFC in cognitive control within an explicitly computational framework. He proposed that the PFC housed a supervisory attentional system (SAS) – a mechanism by which PFC coordinates complex cognitive processes. Shallice's theory was described in terms of a production system architecture. This has appeal, as it relates the executive functions of the frontal cortex to the well-characterized mechanisms of other production system theories that include the active representation of goal states to coordinate the sequences of production firings involved in complex behaviors (e.g., Anderson, 1983). One feature of goal representations is that they must be maintained actively throughout the course of a sequence of actions to direct behavior effectively. This coincides with the observation that PFC appears to be specialized for the active maintenance of task-relevant information. Thus, it is possible that PFC is specialized for the maintenance of a *particular type* of information, as a means of executing control over performance.

While Shallice's theory was not implemented originally as a functioning model, Kimberg and Farah (1993) proposed a model of frontal function – also using a production system architecture – that simulated performance in a variety of tasks considered to rely on frontal lobe function (including the WCST), and illustrated that damage to this component of the model produced impairments similar to those observed in patients with frontal damage. However, while such models have produced insights into the functional role of PFC in cognitive control, their components do not have a transparent mapping on to specific neurobiological mechanisms. Neurobiological plausibility is not a requirement, per se, of a theory that seeks to explain the cognitive functions of PFC. Nevertheless, the question of how goal-directed behavior arises from the firing of millions of neurons presents a mystery in its own right. Furthermore, understanding how different forms of cognitive impairment arise from different forms of damage to PFC (e.g., the effects of stroke or injury vs. schizophrenia) provides an important motivation for understanding how cognitive control may arise from the specific neurobiological mechanisms housed within PFC.

Recently, investigators have begun to use neural network models to better understand how PFC may carry out its functions. Such models (also known as connectionist or parallel-distributing processing models) simulate the behavioral performance of human subjects (or animals) in cognitive tasks using neurally plausible processing mechanisms (e.g., the spread of activity among simple processing units along weighted connections; see Rumelhart and McClelland, 1986). The goal of this effort is to identify principles of neural function that are most relevant to behavior. Using this approach, Dehaene and Changeux (1989), Levine and Prueitt (1989), and Cohen and Servan-Schreiber (1992) have all described models of prefrontal function, and used these to simulate the performance of normal and frontally damaged patients in tasks that are sensitive to PFC damage, such as the WCST and others. All of these models simulate PFC function as the activation of a set of units that represent the 'rules' of the task; that is, units whose activation leads to a task-relevant response, even when this may not be the one most strongly associated with the stimulus. However, in most models, the PFC units themselves are not responsible for generating the response directly. Rather, they influence the activity of other units whose responsibility this is.

This is clearly illustrated by a model of the Stroop task developed by Cohen et al. (1990).

In the Stroop task (Stroop, 1935), subjects respond to words either by reading them, or by naming the color in which they are displayed. In the critical condition, the word itself conflicts with the color in which it is displayed (e.g., the word 'GREEN' displayed in red). Subjects have no trouble reading such words (e.g., saying 'green'). However, when they are asked to name the color (e.g., say 'red'), they are significantly slower, and sometimes even make errors. This reflects the highly practiced, and therefore prepotent tendency to read written words, which interferes with the ability to name the color of a Stroop conflict stimulus. The ability to name the color in the face of such interference (i.e., to produce the weaker, but task-relevant response) is a simple but clear example of cognitive control.

Cohen et al. (1990) constructed a model of this task, as shown in **Figure 2**. The connections among the units in this model defined two processing pathways, one for word reading and another for color naming. The connections in the word-reading pathway were stronger, capturing the assumption that this was the more practiced task. Because of these stronger connections, information flowing along the word pathway interfered with color naming, simulating the interference effects observed when human subjects perform this task. Indeed, the model's ability to produce a response to the color in the face of such interference required the addition of a set of units (labeled 'Dimension' in **Figure 2**), which provided additional activation of the units in the color-naming pathway. This additional activation biased processing in favor of this pathway, allowing it to compete more effectively with, and prevail over, activity flowing along the stronger word pathway. This biasing effect corresponds precisely to the role of top-down control in neurophysiological models of attention (such as the Biased Competition Model of Desimone and Duncan, 1995), and has been proposed as a mechanism by which PFC exerts control over processing (Cohen and Servan-Schreiber, 1992; Miller and Cohen, 2001). Models such as this have been used to simulate the performance of both normal subjects and patients with frontal damage in a wide range of tasks that tap cognitive functions commonly associated with PFC function, such as working memory, attention, behavioral inhibition, planning, and problem solving.

Figure 2 Model of the Stroop task, showing the pathways for word reading, color naming, and top-down control. Connections between units in different layers are excitatory and within layers are inhibitory (closed circles). Shown with color dimension unit active, biasing color-naming pathway. Adapted from Cohen, J.D., Dunbar, K., McClelland, J.L., 1990. On the control of automatic processes: a parallel distributed processing account of the Stroop effect. Psychology Review 97, 332–361.

Guided Activation as a Method of Control

The Stroop model brings several features of PFC function into focus. First, it emphasizes the view that the role of the PFC in control is modulatory, guiding the flow of activity along pathways in other parts of the brain that are responsible for task performance. For example, activating the color unit does not in itself transmit information about a particular response (red or green). Rather, it simply insures that activity flowing along the color-naming pathway will have a greater influence over the response than activity flowing along the word pathway. In this way, representations within the PFC can function as intentions, rules, or goals (comparable to those in a production system architecture), by setting up the appropriate relationship between a stimulus (or category of stimuli) and an associated response (or set of responses) through the proper guidance of activity along pathways in other parts of the brain. Recent neurophysiological findings regarding the firing properties of neurons in PFC have provided strong support for this view (for a review, see Miller and Cohen, 2001). Recent neuroimaging studies have also provided convergent support, indicating that PFC activity occurs when behavior relies upon explicit knowledge about rules or arbitrarily determined conjunctions of stimulus features (for a review, see Miller and Cohen, 2001). Note that this function is not necessarily restricted to mappings from stimuli to responses, but applies equally well to mappings involving internal states (e.g., thoughts, memories, and emotions). Note also that this function is not necessarily unique to PFC. There may also be more local forms of control, responsive to regionally specific needs for the biasing of processing. However, the wide range of anatomic connections that the PFC shares with virtually all associative areas of the brain places it in a strategic position to guide the flow of activity between and among these other regions (for a review, see Miller and Cohen 2001) – a position well suited to its presumed role in the control of higher cognitive processes.

The emphasis of this guided activation model of PFC on its modulation of other brain areas actually responsible for task execution is consistent with the classic pattern of neuropsychological deficits associated with frontal lobe damage: the individual elements of a complex behavior are usually left intact, but the subject is not able to coordinate them in a task-appropriate way (e.g., a patient, who when preparing coffee, first stirred and then added cream; Shallice, 1982). The guided activation model also captures another critical feature of theories about the role of PFC in executive function: the importance of sustained activity as a critical component of control. For a representation to have a biasing influence, it must be activated. For this influence to endure (e.g., over the course of performing a task), its activity must be sustained. For example, to continue color naming, the activity of the color

unit must be maintained, lest the word begins to dominate processing. Similarly, an increase in the demand for control requires greater or more enduring activity of the corresponding units in PFC. This concurs with accumulating evidence from the neuroimaging literature, that tasks thought to rely on controlled processing consistently engage the PFC (for a review, see Smith and Jonides, 1999). It is also consistent with both behavioral and neuroimaging findings regarding the effects of practice on automaticity and the involvement of PFC. Increased practice on a task should strengthen its underlying pathway, reducing its reliance on control. Indeed, consistent practice on a task reduces the amount of PFC activity observed, and PFC damage can impair new learning but spare performance on well-practiced tasks (for a review, see Miller and Cohen, 2001).

Finally, this approach helps to unify the role that PFC plays in the variety of cognitive functions with which it has been associated, such as selective attention, behavioral inhibition, and executive function in working memory. These can all be seen as varying reflections, in behavior, of the operation of a single underlying mechanism of cognitive control: the biasing effects of representations in PFC on processing in pathways responsible for task performance. For example, selective attention and behavioral inhibition may be viewed as two sides of the same coin: attention is the effect of biasing competition in favor of task-relevant information, and inhibition is the consequence that this has for the irrelevant information (cf. the Biased Competition Model of Desimone and Duncan, 1995). This assumes that inhibition occurs due to local competition between conflicting representations (e.g., between the two responses in the Stroop model), rather than centrally by the PFC. The 'binding' function of selective attention can also be explained by such a mechanism, by assuming that PFC representations can select the desired combination of stimulus features (over other competing combinations) to be mapped on to a response.

Outstanding Questions

The guided activation model provides an integrative and mechanistically explicit framework for considering the role of PFC in cognitive control. At the same time, it brings into focus a number of important and unanswered questions. For example, despite the longstanding observation of delay-period activity for PFC neurons, and the centrality of this property in neural network models of PFC, little is known about the actual mechanisms by which neuronal activity is sustained. This could reflect a cellular property of PFC neurons (e.g., bistability), or a circuit-level phenomenon (e.g., recirculation of activity within the PFC, or between PFC and other structures). Several models have proposed the latter, assuming that representations are maintained in PFC as attractor states (for a review, see O'Reilly et al., 1999). However, neurobiological studies are needed to confirm this hypothesis. A closely related question concerns the mechanisms by which patterns of activity are updated in PFC. These must be able to satisfy two conflicting demands: on the one hand, they must be responsive to relevant changes in the environment; and on the other, they must be resistant to updating by irrelevant changes. Neurophysiological studies suggest that PFC representations are selectively responsive to task-relevant stimuli and robust to interference from distractors (for a review, see Miller and Cohen, 2001). Not surprisingly, two hallmarks of damage to PFC are perseveration (failure to update) and distractibility (inappropriate updating). These observations suggest the operation of mechanisms that insure the appropriate updating of PFC activity in response to behavioral demands.

Recent modeling work has suggested that brainstem dopaminergic systems and the basal ganglia may play an important role both in updating representations in PFC and learning how and when to do so (for a review, see Miller and Cohen, 2001). Other work has suggested that the anterior cingulate cortex – a midline structure within the frontal lobes – may play an important role in monitoring task performance, and identifying the need to allocate control (Botvinick et al., 2001). Such theories make important predictions about the neural mechanisms underlying cognitive control that serve as valuable challenges to future neurobiological research in this area.

An equally fundamental question concerns the nature of representations in PFC and how they arise. For example, the Stroop model assumes there are units that represent each of the two dimensions of the stimulus (color and word), with the appropriate connections to the corresponding pathways. However, are there such units in the PFC for every possible combination of stimulus and response of which tasks may be composed? This seems unlikely. Yet, there must be sufficient representational richness to support the flexibility in behavior that the PFC seems to afford. What principles define this set of representations, how they are organized, and how they are learned are important questions at both the computational and neurobiological levels.

A better understanding of the mechanisms underlying active maintenance may also provide insight into one of the most striking and perplexing properties of cognitive control: its severely limited capacity. This has long been recognized in cognitive psychology (Posner and Snyder, 1975; Shiffrin and Schneider, 1977), and is painfully apparent to anyone who has tried to talk on the phone and read an email at the same time. The resource limitation of cognitive control has played an explanatory role in many important models of human cognition. However, to date, no theory has provided an explanation of the limitation *itself*. This is a *sine qua non* of cognitive control, and, therefore, provides an important benchmark for any theory that seeks to explain its underlying mechanisms.

Finally, it is important to recognize that the PFC is certainly not the only brain structure involved in cognitive control. As noted above, mechanisms similar to those within PFC may operate locally in other parts of the brain. Furthermore, there are certainly other types of mechanisms critical to cognitive control. For example, the mechanisms responsible for keeping an immediate goal in mind (e.g., working on a book chapter) are not likely to be the same ones responsible for realizing long-term goals (e.g., getting the book published). While the former may be guided by representations actively maintained in PFC, the latter almost certainly engages mechanisms of long-term storage. Some suggestions have been made about how the PFC may interact with the hippocampus to orchestrate the storage and retrieval of goal representations at appropriate times (O'Reilly et al., 1999); however, this remains another area in need of further research.

Conclusion

One of the great mysteries of the brain is how purposeful goal-directed behavior emerges from the millions of relatively simple processing units that are its basic computational elements. Behavioral, neuropsychological, and neurobiological data converge on the idea that the frontal lobes play a critical role in cognitive control. Neural network models have begun to suggest how this may be carried out, as sustained patterns of activity within PFC modulate, or 'guide' the flow of activity along pathways in other parts of the brain responsible for performing a task. However, many fundamental questions remain to be addressed. The human brain is arguably the most complex device in the known universe, and its capacity for higher cognitive function continues to be one of its deepest mysteries. Unraveling this mystery stands as one of the most exciting challenges in science, and the rapid development of sophisticated new empirical methods (such as functional brain imaging) and theoretical tools (such as neural network modeling) offer hope that this challenge can be met.

Abstract

Learning is a process of hypothesis testing based on probabilistic models. Children learn through play, observation, and through explicit teaching. The domain-general cognitive abilities of self-regulation and executive function help children succeed in school by setting learning goals, focusing their attention on the learning tasks at hand, resisting temptations, and regulating their emotions. Children's learning strategies show great variability, both within and across individuals. Education should provide children with opportunities of supported exploration and experimentation, intentional demonstration and instruction, as well as guided discovery.

Understanding children's cognitive development lays the foundation for child education. On the one hand, the recent advancement in cognitive development challenges some of the conventional views of how children learn and how they succeed in school; on the other hand, it also provides theoretical underpinning and empirical support for some of the well-recognized ideologies and practices in early education. This article highlights the contributions of cognitive development research to child education in three areas. The first area focuses on domain-specific developmental mechanisms for learning including theory theory and probabilistic learning model, theory of mind, testimony, and conceptual change. The second area is the domain-general developmental mechanisms focusing on self-regulation and executive function, as well as their relation to school readiness and success. Although pretense is arguably associated with both domain-general and domain-specific development, its relation with self-regulation is highlighted. The last area discusses children's learning process itself and the elaborate relation between learning and development.

Domain-Specific Developmental Mechanisms for Learning

Theory Theory and Probabilistic Learning

Children's learning mechanism is a topic deeply embedded in the debate of nature vs nurture. Nativists view learning as unfolding of innate, modulelike structures when triggered by environmental stimuli, while empiricists deny the very existence of abstract, coherent structures and see learning as building associations among information that is context dependent. Rooted in Piaget's constructivism, developmental 'theory theorists' have suggested that the way children learn resembles the process of scientific theory formation (e.g., Gopnik and Meltzoff, 1997). The recent development of the theory theory (Gopnik, 2012) attempts to consolidate the nativists' and the empiricists' views of the mechanism of children's learning by applying probabilistic learning model based on Bayesian statistics. Bayesian statistics conceive that the truth or falsity of propositions is uncertain and the evidence of the true state of the world is expressed as degrees of belief. Statements concerning the causal structures are considered as hypotheses. Prior probability of a hypothesis is specified, and then constantly updated in the light of new data. The probabilistic learning account proposes that young children, even infants, can infer causal structure from statistical information. Structures of the real world can be represented mathematically by generative models that allow the learner to compute the patterns of evidence generated by the structure and make inferences. The learner can also invert that process and learn about the structure of the real world from evidence. What is unique about the probability model is that it helps the learner to pick out the most likely hypothesis among all the hypotheses that are compatible with the pattern of evidence based on probability. Consequently, children are not constrained by the innately determined representations, nor do they start from a blank slate; instead, they are constantly assessing their data and testing hypotheses as scientists do. Learning becomes a process of integrating prior knowledge and new evidence to revise the representations of the world based on experience. In a recent review, Gopnik and Wellman (2012) provided empirical evidence that children from 16 months to 4 years of age adopt the probabilistic learning mechanisms such as informal experimentation through play, imitation, and informal pedagogy in their physical and psychological causal inferences.

One of the most appealing implications of the probabilistic learning account for educators is that it advocates explorative play as informal experimentation to generate causally relevant and informative evidence for children to make causal inferences. Gopnik and Wellman (2012: p. 1095) call this type of learning as 'learning from interventions.' They argued that by intervening first hand, one could rapidly narrow down the number of possible hypotheses in order to search more efficiently. These interventions need not to be systematically controlled experiments. Play, as informal experimentation, is sufficiently systematic to help children actively seek out evidence and discover causal structure. In the education sector, play has long been held as the driving force for learning during early childhood. The probabilistic learning account provides the theoretical underpinning from cognitive development perspective for the play-based learning viewpoint for the first time. Furthermore, this account also backs up the inquiry-based scientific education in general.

Theory of Mind

Children not only learn from firsthand exploration, they also learn new causal relations by observing others' interventions and through imitation. Gopnik and Wellman (2012) argued that the theory formation mechanism of children's learning not only applies to the causal structure of the world, but also the mind of the person teaching them. Indeed, teaching and learning are enterprises involving a theory of mind, the intuitive understanding of one's own and other people's mental states and activities, such as thoughts, beliefs, perceptions, knowledge, intentions, desires, and emotions, and of behavioral consequences of such mental states. A significant developmental milestone during early years of life, the awareness of people's mental life, and its relationship with behavioral outcome, is being proposed to be critical for learning and being taught more generally (Wellman and Lagattuta, 2004).

Recognizing existing differences and changes in knowledge is a theory of mind reasoning skill that is essential in teaching and learning. Young children will not yet be able to assume an intentional stance in learning until they see the possibility of acquiring knowledge. Research on the relationship between theory of mind and teaching and learning (e.g., Frye and Ziv, 2005; Wang, 2010) had shown that young children were sensitive to both the epistemic and motivational mental states in teaching and learning, such as the differences and changes in knowledge state, beliefs about knowledge state, and teaching and learning intentions. Furthermore, children's understanding of teaching and learning developed with their evolving theory of mind. Those who acquired false belief understanding also had a grasp of more sophisticated teaching and learning concepts such as imitation, embedded teaching, and discovery learning. In contrast, younger children who were yet to understand the independent nature of reality and mental representation failed to recognize that the teaching intention embedded in play, and treat pure discovery through coincidence as intentional learning. It seems that young children have mistaken 'learning by doing' as 'learning is doing.'

This line of research has several implications for early education. Firstly, it brought the precursors of metacognition during early childhood to light. Theory of mind enables children to think reflectively on their learning. Along with the developing executive functioning and self-regulation around the same time in life, which is discussed later in this article, these developmental achievements prepare children to become conscious learners with the capacity to actively monitor and regulate their own learning. Secondly, this line of research echoes Vygotsky's idea of social learning. Children learn in a network of knowledge exchange. In addition to firsthand intervention, social interactions between teachers and learners and among learners provide the much needed intentional teaching and learning such as demonstration, instruction, and guided discovery. Last but not least, young children's confusion between doing and learning suggests that effective teaching and learning have to be effortful, with sustained attention control, and working memory resources. Children can be busy all the time with hands-on activities and experiments in classroom. But only when children are mentally engaged in the tasks will they actually start to learn. In order to mentally engage children, teachers need to make the teaching intention and the knowledge state change explicit for them to take full advantage of the teaching event (Frye and Wang, 2008).

Testimony

Sobel (2010) argued that probabilistic learning account is an integration of both bottom-up processes, such as extracting knowledge from observed data, and top-down processes, such as direct instruction. Harris (2002) calls the top-down learning processes as learning from 'testimony.' Children rely extensively on adults' testimony to learn, especially about entities that are not readily observable, such as metaphysical entities like God and tooth fairy, as well as scientific entities like germs and the shape of the Earth. The degree to which children commit to these entities varies according to the exposure they receive about them. More generally, Sobel suggested that children learn causal structures simply by being told. Nevertheless, children do not readily trust everything they are told; instead, they selectively trust particular informants' testimony from an early age. By observing the informants at work, children constantly access the informants' motive, reliability, competence, and knowledgeability when learning; they also compare testimony with their own observation and make sensible choices (e.g., Clément, 2010; Liu et al., 2013).

Testimony research highlights the role of direct instruction, which is compatible with the probabilistic learning account. Gopnik (2012) cautioned the use of direct instruction in teaching by emphasizing a balanced view of pedagogy. On the one hand, children know when they are being taught, which enables them to learn faster and more efficiently. On the other hand, explicit teaching limits the range of possible hypotheses for children to consider. A balanced view should consider direct instruction as one of the tools for teaching, yet at the same time provide examples, anomalies, encourage exploration and experimentation, and ask for explanations. Exploration and experimentation should be supported with appropriate scaffolding.

Conceptual Change

Another contribution of theory theory to child education is conceptual change (Vosniadou et al., 2008). Scientific theories develop in the context of paradigms (Kuhn, 1962), which refer to webs of shared concepts, beliefs, and practices, in the science community. The scientific theory change is not cumulative but revolutionary: old paradigms are rejected and replaced by new ones. The radical changes between theories make it difficult to establish rationally that one is better than another. Theory theory compares the process of children's cognitive development to that of theory development in the science community. Knowledge is acquired in domain-specific, theorylike structures. Conceptual change involves significant changes in concepts and theoretical frameworks. In the process of conceptual change, prior knowledge or misconceptions become stepping-stones toward more accurate knowledge and scientific explanations, although they may coexist with accurate ideas in the explanation and prediction. An individual's understanding can vary across contexts and domains, and there is not necessarily always linear improvement across age.

Conceptual change posits a relatively coherent body of domain-specific knowledge characterized by a distinct ontology and a causality that can give rise to explanation and prediction. Children have a rich set of ideas, conceptual frameworks, and reasoning skills. Organized into different domains, their naive theories explain and predict how things ought to behave, and solve problems. Conceptual change can be either bottom-up or top-down. Some misconceptions will self-correct without instruction as children gain more experience, such as one will not grow into a giant if eat more. These types of conceptual change are conservative and additive, largely unconscious. Yet some aspects of modern scientific knowledge are so counterintuitive that children are unlikely to achieve understanding without instruction, such as germs, particles, and the shape of the Earth. The instruction-induced conceptual changes are usually radical and deliberate. The process involves hypothesis testing, analogy, and metarepresentation, sometime thought experiments.

Rather than simple accumulation of information, proficiency in science is theory building based on prior knowledge and misconceptions. Factual knowledge must be placed in a conceptual framework to be well understood. Children need to learn how concepts are related to each other and their implications and applications. For spontaneous conceptual change, teachers need to provide an enriched environment for children's explorations and scaffold scientific thinking by positing task-appropriate questions at the right moment. For instruction-induced conceptual change, it is important to confront children with conflicts in their framework. Teachers need to focus on a few key concepts and core ideas and explain causality.

Domain-General Developmental Mechanisms for Learning

Self-Regulation and Executive Function

If theory theory is a domain-specific learning mechanism, self-regulation is rather a broad construct that lays the foundation for development across all domains. Self-regulation is an integrated, multidimensional construct that incorporates a broad range of psychological processes including biological processes, attention, emotion, behavior, and cognition. As a goal-directed behavior over time and in varying contexts, self-regulation generally entails three aspects: representing goals, motivation to achieve goals, and capacity to achieve goals despite of obstacles. Executive function is a construct subserving self-regulation that is discussed mainly by cognitive psychologists. It encompasses several distinctive cognitive constructs, including working memory, mental set shifting, and inhibitory control (Hofmann et al., 2012). While the measures for self-regulation can be both teacher or parent reports or behavior tasks such as delay of gratification, executive function measures are mainly behavioral tasks for children, including working memory tasks, stroop-type tasks for measuring inhibitory control, and set shifting tasks such as the Dimensional Change Card Sort (DCCS) task (Zelazo et al., 2003).

School Readiness and Success

While the focus of school readiness has traditionally been on academic preparedness, more recently it has been recognized as a multidimensional construct that includes cognitive and social emotional competences such as self-regulation (Blair, 2002) and theory of mind (Astington and Pelletier, 2005). The very components of self-regulation such as attention, inhibitory control, planning, abiding by rules, and working memory can explain why children's ability to self-regulate is strongly related to their performance in school. Virtually any effortful academic task requires attention control ability including focused attention, and suppression of interference or conflict from other, irrelevant information, which improves significantly during the early school years. Blair (2002) proposed that inefficient emotional regulation inhibits the use of higher order cognitive regulation, therefore affects academic achievement. Behavioral regulation supports the development of internally driven conduct norms like sitting quietly in the classroom, which children need in order to function independently in the school. Cognitive regulation measured by executive function tasks not only enables children to hold multiple stimuli and/or perspectives in mind and switch between two incompatible classification rules flexibly, it also moderately correlates and predicts later theory of mind development (Devine and Hughes, in press) that in turn affects children's learning.

Both correlational and longitudinal data have demonstrated the connection between self-regulation and academic success. A recent meta-analysis (Allan et al., 2013) found a modest overall relation between self-regulation and the academic skills of preschool and kindergarten children. Consistent with the distinction between the cognitive-laden cool self-regulation and the affect-laden hot self-regulation, academic skills were found to be more associated with measures of cool self-regulation than with those of hot self-regulation. Both behavior tasks and teacher reports were related to academic skills. Furthermore, self-regulation in general was more strongly associated with early math skills than with early literacy skills. Longitudinal data showed that self-regulation abilities strongly predicted later success in school and life. Self-regulation measured in preschool predicted children's academic success in the early primary years, even when variations in their intelligence or family backgrounds were controlled (e.g., Blair and Razza, 2007).

Class activities that demand higher levels of executive control might mask young children's mastery of the academic skills that the activities aim to assess. Evidence from adult literature suggests that 'depleted' self-control subsequently lowered one's cognitive function (Baumeister et al., 2007). Knowing this challenge children face in learning, teachers ought to consider the general cognitive demands of a lesson in addition to its content-specific requirements in lesson planning. There is also evidence that attention control skill is trainable for children as young as 4–6 years of age using computer games (Rueda et al., 2005) that might suggest an alternative pathway for academic enhancement of general executive function training.

Pretense

The cognitive flexibility required for self-regulation and executive function is readily available in children's pretend play. Assuming a pretend character in play helps children to take on another perspective. Even more so, when the child steps out

from the play frame to plan, coordinate, and negotiate roles and play scenarios, she attends to other players' perspective while assuming her own identity. In the process of back and forth shifting of perspectives, children practice executive control skills related to inhibiting the reality, holding multiple perspectives at the same time, and switching from one perspective to another flexibly. Carlson and associates (cf Carlson and White, 2013) found children's pretend play was indeed related to executive function measured by DCCS, controlling for working memory and verbal ability.

Carlson and White (2013) brought attention to the psychological distancing effect of symbolic thought. They argued that substituting direct experiences with symbols distances one from the sought after 'hot' reward in the delay of gratification tasks, which allows behavior to be controlled in light of the symbol rather than the stimulus itself. In the Less is More task, children need to indicate that they want the tray with less treats to actually get the tray with more treats. Young children found it rather difficult to resist the temptation of wanting the tray with more treats. When symbols were used to represent the real treats, however, young children's performance significantly improved. Attention control strategies such as the generalization from the symbolic representation to the real stimuli help children to manage the delay more efficiently.

Pretend play and symbolic representation and reasoning carry a lot of weight in early childhood education. The idea that these intuitive teaching practices actually support higher order executive function is reassuring and encouraging. A study by Bodrova and Leong (2007) had found that teacher-supported socio-dramatic play was an effective strategy for developing preschool children's self-regulation. More research is needed to fully understand the link between good teaching practices and children's cognitive development.

Pretense is believed to facilitate theory of mind development due to its metarepresentational nature (Leslie, 1987). Rich in counterfactual reasoning, it is also essential to probabilistic model learning (Walker and Gopnik, 2013). However, a recent comprehensive review (Lillard et al., 2013) found that the empirical evidence on the impact of pretend play on children's cognitive and social development was inconclusive. More rigorous research is needed to fully understand how pretend play facilitates learning. Meanwhile, play-based learning, according to Lillard et al., is still the most positive means yet known for child development.

How Do Children Learn?

So far the article has been focusing on the developmental mechanisms for learning. How about the learning process itself? How do children really learn? According to Siegler (2000), research on children's learning has reemerged after the decline of associationism focusing on learning of meaningful concepts and skills that are important in children's lives. One of the leading theories on children's learning is the overlapping waves theory (Siegler, 1996, 2000, 2005) that centers on the variety of strategies and ways of thinking in learning and problem solving. According to this theory, multiple approaches coexist simultaneously, with new strategies being added and old strategies cease to function sometimes, and certain single strategy could exist for a prolonged period of time, even after more advanced strategies emerge. It emphasizes cognitive diversity in learning, both with individuals and across them, even within an individual solving the same problem in different trials or within the same trial. A schematic depiction of the overlapping waves model (Figure 1) outlines the diversity of learning strategies in terms of the levels of sophistication, the timing, and the complex relationships among the strategies.

Figure 1 Schematic depiction of the overlapping waves model. Adapted from Emerging Minds: The process of change in children's thinking (Figure 4.4: p. 89), by Siegler, R.S., 1996. Emerging Minds: The Process of Change in Children's Thinking. Oxford University press, New York, Oxford. With permission from Oxford University Press, USA.

To study the detailed learning process with ecological validly, microgenetic methods of learning are adopted in the overlapping waves theory. These methods make dense observations in relation to the rate of change over a period of rapidly changing competence and intense analysis of these observations. The richness of the microgenetic data allows the overlapping waves theory to analyze learning along five dimensions, the path, rate, breadth, source, and variability of learning.

One of the major contributions of the overlapping waves theory is that it marries learning and development. Siegler argues that the learning and development processes have a lot in common in terms of variability, choice, and change, therefore cannot be distinguished from one and another. Some of the learning analyses echo the age-related changes described by developmentalists like Piaget. Siegler calls his theory as a developmental approach to learning that integrates both qualitative and quantitative changes. The educational implication of microgenetic analysis of learning is that it provides evidence for how teaching instruction unfolds children's learning therefore is helpful for designing more effective future instructions.

Conclusions

The learning process is inseparable from child development. Learning is a process of hypothesis testing based on probabilistic models. Children learn through play, observation, and through explicit teaching, during which children are constantly

testing and adjusting their hypotheses based on data collected from spontaneous experimentation, observation of other people's intervention, as well as knowledge and intentional attribution in teaching. The domain-general cognitive abilities of self-regulation and executive function help children succeed in school by setting learning goals, focusing their attention on the learning tasks at hand, resisting temptations, and regulating their emotions. Children's learning strategies show great variability, both within and across individuals. Teaching and learning are goal-directed, mindful, and effortful enterprises. Education should provide children with opportunities of supported exploration and experimentation, intentional demonstration and instruction, as well as guided discovery.

Abstract

Jean Piaget, the great pioneer of this field in the twentieth century, described children as active learners who, through interactions with their environments, construct a complex understanding of the world, from the sensorimotor stage in infancy to the logical and formal operations stage in adolescence. However, Piaget underestimated the cognitive capabilities of infants, preschoolers, and elementary schoolchildren and overestimated the capabilities of adolescents and adults, which are often biased by illogical intuitions and overlearned strategies. We highlight several discoveries in the field from Piaget to the new theoretical ideas and empirical research reported over the last three decades. The crucial question is to understand why, despite rich precocious knowledge about physical and mathematical principles observed in infants and young children (from object principle to pure reasoning on abstract principles), older children, adolescents, and adults often have poor reasoning ability. We state that inhibition of less sophisticated solutions (or heuristics) by the prefrontal cortex is a critical component of children's conceptual insights associated with more advanced Piagetian stages. We conclude the article with the issue of cultural variations and suggestions for educational policy.

The scientific study of cognitive development in young children traces its roots back to Jean Piaget, a pioneer of this field in the twentieth century (Piaget, 1954, 1983). Piaget described children as active learners who, through numerous interactions with their environments, construct a complex understanding of the physical world around them. From infancy to adolescence, children progress through four psychological stages: (1) the sensorimotor stage from birth to 2 years (when cognitive functioning is based primarily on biological reactions, motor skills, and perceptions); (2) the preoperational stage from 2 to 7 years (when symbolic thought and language become prevalent, but reasoning is illogical by adult standards); (3) the concrete operations stage from 7 to 12 years (when logical reasoning abilities emerge but are limited to concrete objects and events); and (4) the formal operations stage at approximately 12 years (when thinking about abstract, hypothetical, and contrary-to-fact ideas becomes possible). Like the logician or mathematician, the child 'models' objects, their properties, and their relations through a succession of cognitive frameworks, from primary biological reactions and motor skills to high-order formal thinking. According to Piaget, after the age of 12, children model a formal hypothetico-deductive logic that resembles the rational logic of scientists and mathematicians. Piaget was the first psychologist to take children's thinking seriously. His genius was based on the idea of building his child development theory on triple roots in epistemological, biological, and logicomathematical foundations. Consequently, Piaget is now recognized as one of the precursors of cognitive science during the last century (Fischer and Kaplan, 2003).

Piaget underestimated the cognitive capabilities of infants, preschoolers, and elementary schoolchildren, and he overestimated the capabilities of adolescents and adults, which are often biased by illogical intuitions and overlearned strategies (or heuristics) they fail to inhibit (Houdé, 2000; Kahneman, 2011). During the last three decades, detailed behavioral studies of children's problem solving led to a reconceptualization of cognitive development, from discrete Piagetian stages to one that is analogous to overlapping waves (Siegler, 1996, 1999). The latter is consistent with a neo-Piagetian approach of cognitive development, in which more and less sophisticated solutions compete for expression in the human brain. In this approach, inhibition of less sophisticated solutions by the prefrontal cortex is a critical component of children's conceptual insights associated with more advanced Piagetian stages (Houdé et al., 2000, 2011; Poirel et al., 2012). At any point in time, children and adults potentially have available to them heuristics (i.e., intuitions) and logicomathematical algorithms, or as Kahneman described, multiple levels of 'thinking fast and slow' (Kahneman, 2011). Heuristics are rapid, often global or holistic, useful strategies in many situations, *but sometimes they are misleading*, whereas algorithms are slow, demanding, and analytical strategies that *necessarily lead to a correct (i.e., logical) solution in every situation*. In general, children and adults prefer using fast heuristics spontaneously, but that choice does not indicate that they are illogical per se (Houdé, 2000) or that they are 'happy fools' (De Neys et al., 2013). Psychologists had to be careful to avoid false negatives (Gelman, 1997), which is a strong tendency to say that those children or adults who fail a task are incompetent in the target domain of knowledge. A 'presumption of rationality' is sometimes the best assessment.

Contrary to Piaget's theory, infants learn more about the outside world through information that is captured by their perceptual systems than through motor skills development (Baillargeon, 1995; Mandler, 1988; Spelke, 2000). Infant cognition studies evaluated both the capacity to interpret sensory data and the faculty for understanding and reasoning about complex events. In the last 10 years, theoretical ideas and empirical research in the field have demonstrated that very young children's learning and thinking mechanisms do remarkably resemble the basic inductive processes of science, i.e., probabilistic models and Bayesian learning methods (Gopnik, 2012). Infants can implicitly reason statistically (Téglás et al., 2011). From this point of view, the very young child is already seen as a 'scientist in the crib' (Gopnik et al., 1999).

We highlight several discoveries in the field, from Piaget to the new theoretical ideas and empirical research. We will conclude the article with the issue of cultural variations and suggestions for educational policy.

Beyond Piaget's Description of Infant Cognition

The most important advances were associated with a change in methodology, made possible by the use of videotapes and computers. Instead of analyzing infant action skills (or 'schemes'), as advocated by Piaget, the infant's gaze behavior was examined. Experiments using the visual habituation technique and recordings of visual fixation time were conducted to study infant reactions to novelty and the detection of unexpected (or 'impossible') events. These experiments led to the discovery of early abilities unknown to Piaget, such as object unity and object permanence by the age of 4 or 5 months (along with other physical principles or core knowledge: cohesion, contact, continuity, containment, and support; Baillargeon, 1995; Spelke, 2000; Spelke et al., 1995), the existence of numerical abilities by that same age (Wynn, 1992, 1998), and 'pure reasoning' through statistical expectations by the age of 12 months (Téglás et al., 2011). Other studies have described neonatal imitation of social partners during the first few days of life and cross-modal perception in the early months (Meltzoff and Moore, 1977; Meltzoff and Prinz, 2002). Moreover, new discoveries about early social cognition, which were underestimated by Piaget, showed that very young children can perform moral evaluation of others' actions: 6- and 10-month-old infants prefer an individual who helps others to one who hinders others, prefer a helping individual to a neutral individual, and prefer a neutral individual to a hindering individual (Hamlin et al., 2007). These findings constitute evidence that preverbal infants have the capability to assess individuals on the basis of their behavior toward others. This capability may serve as the foundation for moral thought and action. By the age of 12 months, infants know that only intentional agents can create physical order between objects (Newman et al., 2010). Finally, in the same vein, new discoveries demonstrated that preverbal 15-month-old infants can understand false beliefs in theory-of-mind tasks, which were adapted for the visual detection of unexpected psychological events (Onishi and Baillargeon, 2005). In the next section, we will focus on strictly cognitive development, from early object principle to pure reasoning on abstract principles.

From Early Object Principle to Pure Reasoning on Abstract Principles

Children as Physicists: Early Object Permanence

Piaget described children as active learners who, through numerous interactions with their environments, construct an increasingly complex understanding of the physical world around them. In infancy, the first step of this construction is object permanence (Piaget, 1954). We are indebted to Piaget for his clear statement of the problem of how objects act as the basic unit for constructing reality: Does an object continue to exist for infants once it is out of sight? Does it have permanence outside of the immediate experience? Six substages (within Stage 1: Sensorimotor) stand out from Piaget's observations; these substages delineate the laborious path that infants take toward object permanence, essentially during the first year of life.

According to Piaget, the systematic search for a disappeared object does not begin until Substage IV of sensorimotor development, at approximately 8 or 9 months. This substage still suffers from the location error, which can be demonstrated using the following device: the experimenter places the infant in front of two screens (A and B) that are equally easy to reach, and he hides an object under screen A. The 8- to 9-month-old has no trouble finding the object. After a few repetitions of this situation, the object is conspicuously transferred from under screen A to under screen B. If there is a delay before the infant can respond, he continues to look for the object under screen A: this is the so-called A-not-B error. The Piagetian interpretation is that infants have not yet mastered the true object permanence principle. It is not until the end of the first year that this principle is acquired, and hence the disappearance of the A-not-B error at about 12 months (with a few remaining refinements during the second year). This interpretation is contested today in light of new data on the existence of object permanence by the early age of 4 or 5 months. The new data came with a change of methodology from the Piagetian study of the infant's action skills to the post-Piagetian study of the infant's looking behavior, i.e., analysis of perceptual activity measured by visual fixation time.

With this new approach, Baillargeon and colleagues (Baillargeon, 1987, 1995; Baillargeon et al., 1985) provided evidence of the early existence of object permanence using the so-called impossible-event paradigm (or violation-of-expectation paradigm). This famous experimental procedure runs in two phases: (1) The infant is facing a presentation device with a screen fastened to its base by a hinge in such a way that the screen can be rotated 180° along the horizontal axis. The infant is habituated to the alternating backward–forward rotation. (2) A box is placed behind the screen's rotation axis in such a way that the screen can now only be rotated 112°, at which point it completely hides the box (the disappeared object). The infant is then shown a possible event, a 112° rotation of the screen, and an impossible event, a 180° rotation. In Phase 2, 4- and 5-month-old infants look longer at the impossible event than at the possible one, although the impossible event is identical to the habituation situation (180° rotation) and the possible event is new (identical results have been found in infants at three and a half months of age, but not in all infants). Baillargeon concluded that 4- and 5-month-old infants realize that the event is impossible, which suggests that they can conceive of the violated property, namely, the permanence of the box hidden by the screen. By this young age, the concept of object permanence may already be in place, along with the cohesion principle (experiments on this problem were conducted by Baillargeon and other investigators: Baillargeon, 1995; Baillargeon and DeVos, 1991). Moreover, Wynn (1992, 1998) showed that in protonumerical activities, a permanent object (one that is completely out of sight) can be integrated by 4- or 5-month-old infants as a physical entity that is connected to other discrete and quantifiable entities.

The divergence between the experimental data just presented and Piaget's theory, closely tied to the paradigms used, is problematic for infant psychologists. If by 4 or 5 months of age, there is the concept of object permanence in infants, how can one explain the A-not-B error classically found in 8- to 12-month-old children? For some authors, this question is not a critical one, whereas for others, it is one of the fascinating puzzles of the psychology of cognitive development (Houdé, 2000). A range of interpretations have been proposed, along with ingenious experimental situations, e.g., the role of memory capacity, spatial organization, and motor programming constraints (motor perseveration and inhibition). One of the most impressive interpretations was proposed by Diamond (1991, 1998); Diamond and Goldman-Rakic (1989) in their conclusion of a comparative study in neurocognitive animal psychology (conducted on monkeys after prefrontal cortex ablation). Diamond and Goldman-Rakic suggested that the location error made by 8- to 12-month-old infants results from ineffective inhibition of a prepotent gesture (moving toward A) brought about by the insufficient development of the prefrontal cortex. Single-cell recordings in monkeys (Watanabe, 1996) and the neural models devised by Dehaene and Changeux (1989) corroborated the hypothesis by Diamond and Goldman-Rakic that the frontal system plays a decisive role. Complementary studies by Bell and Fox (1992) established a relationship between the electroencephalographic recordings of the frontal system and the cognitive development of infants, in particular, their performance in the A-B situation. The recordings confirmed the existence, in infants, of the link between the A-not-B error and the frontal system established by Diamond and Goldman-Rakic for nonhuman primates. The authors concluded that success in the A-B situation is achieved through inhibition of the initial programmed gesture, in conjunction with a sufficient memory capacity and the ability to resist distraction during the delay (several experimental findings, however, argued against the hypothesized role of frontal inhibition, and thus of the perseveration of a to-be-inhibited gesture, as the sole explanatory factor; for meta-analyses, see Marcovitch and Zelazo, 1999; Wellman et al., 1987).

Children as Mathematicians: Early Numerical Abilities

A heated debate topic in psychology is how children come to understand numbers? Piaget's answer was that number is constructed in children through the logicomathematical synthesis of classification and seriation operations. Number borrows its inclusion structure from classes (1 is included in 2, 2 in 3, etc.); because it disregards qualities by transforming objects into units, it brings a serial order into play, the sole means of distinguishing one unit from the next: 1 then 1, then 1, etc. The serial ordering of units is combined with the inclusion of the sets that result from their union (1 is included in 1 + 1, 1 + 1 is included in 1 + 1 + 1, etc.) to constitute number. The task Piaget used was the conservation of number. When children are shown two rows of objects that contain an equal number of objects but that differ in length (because the objects in one of the rows have been spread apart), young children think the longer row has more objects. Piaget's interpretation was that preschool children are still fundamentally intuitive (their reasoning is illogical by adult standards), or as he called them, 'preoperational' (Stage 2), and hence limited to a perceptual way of processing information (based on length or, in certain cases, on density). At the age of 6 or 7 years, children understand the equivalency of quantities, regardless of apparent transformations. At this point, they are called 'operational' or 'conserving' (Stage 3), the criterion for mastery of number. Piaget also worked on determining whether the conservation of number develops simultaneously with inclusion (classification) and order relations (seriation).

After this founding work on the genesis of number, research in this domain proliferated, and criticisms of Piaget's theory were far from scarce. First, the synchronous development of classification, seriation, and conservation was not validated in experimental verifications. Second, it became clear that Piaget's view of the logicostructural aspect of number is overly polarized and overshadows the more functional aspects of numerical development, such as counting.

A radical change in perspective began with Gelman (Gelman and Meck, 1983; Gelman et al., 1986), who not only turned the attention toward counting but also postulated the early existence of five fundamental principles of counting: stable order (order of the number words), strict one-to-one correspondence (between the number words and the items counted), cardinality (the number word corresponding to the last item counted is equal to the total number of items), abstraction (any kind of item can be counted), and order irrelevance (items can be counted in any order). Gelman demonstrated the presence of these principles in young children by having them say whether they thought a doll was counting correctly or incorrectly. Knowledge or lack of knowledge of a given principle was deduced from whether the child detected the corresponding type of counting error (unstable order, violation of the one-to-one correspondence, cardinal number referred to by an ordinal word number, etc.). The results indicated that 3-year-old children have already acquired the basic principles of counting. This led Gelman to distinguish three components in the ability to count: a conceptual component ('knowing why' or understanding the five principles), a procedural component ('knowing how' or understanding the structure and order of counting), and a utilization component ('knowing when' or understanding the relevance of using the first two components in a given context). Defending the principles-before-skills hypothesis, Gelman suggested that the numerical difficulties of preschool children lie essentially in the procedural and utilization components. Another of Gelman's original contributions was her use of the so-called magic task to demonstrate that 3- to 4-year-old children are surprised by transformations that affect the cardinal number of a set (adding and subtracting items) but not by transformations that do not (spreading and grouping) (Gelman, 1972). She concluded that despite their failure in Piaget's conservation of number task, the children at this age are already capable of seeing through irrelevant transformations and treating the number of items as invariable (for a seminal study on this point, see Mehler and Bever, 1967). This new conclusion was corroborated by the discovery of the perception of numerical invariance in neonates (Antell and Keating, 1983) and in 5- and 8-month-old infants (Loosbroek and Smitsman, 1990; Lipton and Spelke, 2003).

The most striking example of infants as 'mathematicians' is found in the famous work by Wynn (1992). Wynn recorded the looking time of 4- and 5-month-old infants in the 'impossible-event' procedure (or violation-of-expectation procedure) and demonstrated that infants were surprised by (looked longer at) impossible numerical events (e.g., $1 + 1 = 1$ and $1 + 1 = 3$, or $2 - 1 = 2$) but were not surprised at the corresponding possible events ($1 + 1 = 2$ and $2 - 1 = 1$) (the events were staged with Mickey Mouse figures). She concluded that infants are endowed with a mechanism that calculates the exact outcome of simple arithmetic operations. She claimed that infants at this age are already able to encode ordinal information and possess genuine numerical concepts that cannot be reduced to holistic percepts derived from a pattern recognition process (for a brain imaging confirmation of Wynn's results, see Berger et al., 2006). Like Gelman's stance, Wynn's position is strong and seems to run counter to what we know about the numerical difficulties of preschool children. Wynn's empirical results are robust and consistent (Wynn, 2000), but they have sparked theoretical debates (Simon, 1997, 1998). The task of the following research was to devise a developmental model of logicomathematical operations (conservation, counting, and elementary arithmetic) that accounts for both early abilities (Gelman, Wynn, etc.) and late inabilities (Piaget), without denying the reality of the former but raising the question of the factors that explain the latter (see Section What Develops? Heuristics, Algorithms, Cognitive Control, and Inhibition of Misleading Strategies).

Children as Bayesian Statisticians: Early Reasoning Abilities

All of the discoveries summarized before and for most of them achieved during the 1980s and 1990s are key examples that illustrate the post-Piagetian revolution in our understanding of early cognitive development. A new trend in the field is to see children as Bayesian statisticians, i.e., thinkers who already infer abstract hierarchical structure from data. According to Gopnik (2012), if children learn in this way, they could drastically revise their initial representations of the world on the basis of their experience, as scientists do. In this framework, researchers have recently shown that infants and young children not only detect statistical patterns but also use those patterns to test causal hypotheses about objects and people. For example, using a 'looking-time' technique, Xu and Garcia (2008) showed that 8-month-old infants were sensitive to statistical patterns in a ping-pong ball experiment. In this study, the experimenter showed the infants a box full of white and red balls. She closed her eyes and randomly took several balls from the box and put them in a small bin. If the sample was random, then the distribution of balls in the bin should match the distribution of the balls in the box. The infants saw a sample that either matched (i.e., expected event) or did not match (unexpected event) the probabilistic distribution, and they looked longer at the nonmatching sample. In a control condition, the infants saw the same sequence of events, but the experimenter took the balls out of her pocket rather than from the box, and the looking-time difference disappeared.

In the same vein, a subsequent study by Xu and colleagues has demonstrated that children under 2 years of age could infer an underlying mental state, i.e., a 'preference' from a statistical pattern (Kushnir et al., 2010). Another group of researchers illustrated a type of 'pure reasoning' in 12-month-old infants (Téglás et al., 2011). Using complex displays of multiple moving objects, this elegant study showed that infants' probabilistic reasoning is surprisingly rich, powerful, and coherent: infants form time-varying expectations about future events that are a systematic and rational function of several stimulus variables, such as the number of objects, their physical arrangement, and the duration of their occlusion. Infants' looking times are consistent with a Bayesian ideal observer embodying abstract principles of object motion. The power and originality of Bayesian inference are to consider both new evidence and the prior probability of hypotheses through a generative mathematical model, such as a map or tree structure or a graphical network. This gives Bayesian reasoning a combination of stability and flexibility for learning several patterns of evidence rather than others, such as a particular set of visual images, or spoken sentences, or statistical contingencies between events.

Pure and abstract reasoning starts earlier than Piaget had predicted in his stages theory (Stage 4 for formal reasoning operations in adolescents). Hence, all of these new theoretical ideas and empirical research on infancy and early childhood refine one old and simple question (see Karmiloff-Smith, 1992, for a discussion of Fodor's nativism opposed to Piaget's constructivism): Finally, *what develops* after and beyond this rich first set of cognitive abilities?

What Develops? Heuristics, Algorithms, Cognitive Control, and Inhibition of Misleading Strategies

The crucial question now is to understand why, despite these precocious abilities about physical and mathematical principles, older children, adolescents, and adults so often have poor reasoning ability. How might we explain the systematic errors observed in humans at all stages of their cognitive development by Piaget (1954, 1983) in children and by post-Piagetian experimental psychologists of reasoning in adults (Evans, 1989, 2003; Kahneman, 2011; Kahneman et al., 1982; Kahneman and Tversky, 2000)?

How might we explain the famous number-conservation error observed in children until the age of 7 by Piaget and, after him, by all developmental psychologists around the world? It is an intriguing question because we know today that very young children are already capable of treating the number of items as invariable through irrelevant transformations (Antell and Keating, 1983; Gelman, 1972; Loosbroek and Smitsman, 1990; Mehler and Bever, 1967; Lipton and Spelke, 2003) and that they possess other protonumerical skills (Gelman and Meck, 1983; Gelman et al., 1986; Wynn, 1992, 1998). One of the main current explanations is that children learn heuristics, which are often useful in a large set of situations, but fail to inhibit them when, contrary to general practice, they are misleading (Houdé, 2000). In the case of Piaget's number-conservation algorithm, the overlearned competing heuristic is 'length-equals-number' (Houdé and Guichart, 2001). This new theoretical approach is in line with Diamond's explanation of the A-not-B error in infants (see Section Children as Physicists: Early Object Permanence) and assumes that cognitive development relies not only on the

acquisition of knowledge of incremental complexity (Piaget, 1983) but also on the ability to inhibit previously acquired knowledge (Bjorklund and Harnishfeger, 1990; Dempster and Brainerd, 1995; Diamond, 1991, 1998; Harnishfeger, 1995; Houdé, 2000). Increasing evidence shows that the ability to inhibit previous knowledge is critical for developmental milestones, such as those defined by Piaget's theory (Houdé, 2000). Inhibitory control of misleading strategies, an executive function performed by the prefrontal cortex, has been claimed necessary for acquisition and use of motor or cognitive algorithms in the fields of object permanence in infants (Bell and Fox, 1992; Diamond, 1991, 1998; Diamond and Goldman-Rakic, 1989), number conservation and class inclusion in preschool and schoolchildren (Borst et al., 2012, 2013; Houdé and Guichart, 2001; Perret et al., 2003), and logical reasoning in adolescents and adults (Houdé, 2007; Houdé and Tzourio-Mazoyer, 2003; Houdé et al., 2000).

One of the challenges of today's developmental research, in all domains of cognition ranging from motor programming to high-order logical reasoning, is to account not only for a general and incremental process of coordination-activation capacities of structural units, schemes, or skills through ages and stages (Piaget, 1983, and all the 1980s neo-Piagetians: see the review book by Demetriou, 1988) but also for a general process of selection-inhibition of competing strategies, i.e., heuristics (or intuitions) and logicomathematical algorithms, occurring with different weights at any point in time, depending on the context, in a nonlinear dynamical system of growth (Houdé, 2000; Siegler, 1996, 1999). Such cognitive model introduces less regular developmental curves containing perturbations, bursts, and collapses. O'Reilly (1998) described six principles for biologically based computational models of cognition, one of which is inhibitory competition (see also Johnson, 2010). Resolving this 'inhibition issue' is an important task for both developmental psychology and cognitive neuroscience. The most compelling magnetic resonance imaging (MRI) reports of structural changes with brain development during childhood and adolescence showed a sequence in which the higher-order association area, such as the prefrontal cortex sustaining inhibitory control, matures last (Casey et al., 2005). The sequence in which the cortex matures parallels the cognitive milestones in human development. First, the regions subserving primary functions, such as motor and sensory systems, mature the earliest; the temporal and parietal association cortices associated with basic language skills and spatial attention mature next; and the last to mature are the prefrontal cortex and its inhibitory-control ability.

Using fMRI (functional MRI), from this theoretical perspective, we reexamined what occurs in the developing brain when schoolchildren are tested for their performances in Piaget's number-conservation task. Remember that when children are shown two rows of objects that contain an equal number of objects but that differ in length (because the objects in one of the rows had been spread apart), young children think that the longer one has more objects. Piaget's interpretation was that preschool children are still fundamentally intuitive (their reasoning being illogical by adult standards), or as he called them, 'preoperational' (Stage 2), and hence limited to a perceptual way of processing information (here, based on length or, in certain cases, on density). When they are approximately 6 or 7 years old, children understand the equivalency of quantities, regardless of apparent transformations. At this point, they are called 'operational' or 'conserving' (Stage 3), the criterion for logicomathematical mastery of number. Our new hypothesis was that their main cognitive difficulty (beyond logicomathematical cognition per se) was to efficiently inhibit through their prefrontal cortex the overlearned 'length-equals-number' strategy, a heuristic that is often used both by children and adults in many school and everyday situations.

In a first fMRI study, we found that the cognitive change allowing children to access conservation (i.e., the shift from Stage 2 to Stage 3 in Piaget's theory) was related to the neural contribution of a bilateral parietofrontal network involved in numerical and executive functions (Houdé et al., 2011). These imaging results highlighted how the behavioral and cognitive stages that Piaget formulated during the twentieth century manifest in the brain with age. In a second fMRI study (Poirel et al., 2012), we demonstrated that the prefrontal activation (i.e., the blood-oxygen-level-dependent signal) observed when schoolchildren succeeded at the Piaget's number-conservation task was correlated to their behavioral performance on a Stroop-like measure of inhibitory function development (Wright et al., 2003). These new results in schoolchildren fit well with previous brain imaging data from our laboratory showing a key role of prefrontal inhibitory-control training when adolescents or adults (belonging to Stage 4 in Piaget's theory) spontaneously fail to block their perceptual intuitions (or bias, heuristics) to activate logicomathematical algorithms (i.e., deductive rules) in reasoning tasks (Houdé, 2007; Houdé et al., 2000).

If we have 'two minds in one brain' as stated by Evans (2003) or, in other words, two ways of thinking and reasoning, i.e., 'fast and slow' (Kahneman, 2011), currently called 'System 1' (intuitive system) and 'System 2' (analytic system), then the crucial challenge is to learn to inhibit the misleading heuristics from System 1 when the more analytic and effortful System 2 (logicomathematical algorithms) is the way to solve the problem (Borst et al., 2013; Houdé, 2000). Within this post-Piagetian theoretical approach, we can now understand why, despite rich precocious knowledge about physical and mathematical principles observed in infants and young children (from object principle to pure reasoning on abstract principles), older children, adolescents, and adults so often have poor reasoning. The cost of blocking our intuitions is high and depends on the late maturation of the prefrontal cortex. Moreover, this executive ability remains delicate throughout our lifetime, and adults may sometimes need 'prefrontal pedagogy' to learn inhibiting intuitive heuristics (or biases) in reasoning tasks (Houdé, 2007).

An innovative research question now is to better understand the cognitive roots of such powerful heuristics (intuitions and bias from System 1) that children and adults have so much difficulty inhibiting in some cases. New heuristics may appear and be overlearned at any time in the course of development (Houdé, 2000) because our brain is an irrepressible detector of regularities from its perceptual and cultural environment. For example, preschool children (more than infants) are often exposed, in 'math books' in the classroom or in everyday scenes, to patterns of objects in which number and length covary (e.g., the 1–10 Arabic numbering series is frequently

illustrated by increasing lines of drawn animals or fruits: one giraffe, two hippopotamus, three crocodiles, and so on), hence the overlearned and misleading 'length-equals-number' heuristic, which is overactivated in Piaget's conservation of number task. A new avenue of research would be to assess the role of early sensitivity to statistical patterns (i.e., probability of hypotheses) and Bayesian inference (Gopnik, 2012) in the psychological construction of perceptual, motor, and cognitive heuristics. Moreover, the power of Bayesian learning (see the previous section on this topic) might require, in some conflict situations, a strong antagonist process of inhibition for blocking heuristics when they are misleading.

Cultural Variations

In the past, there has been research investigating the universality of Piaget's stages, from infancy (Stage 1: the sensorimotor stage) to adolescence (Stage 4: the formal operations stage). According to Piaget, cultural factors should only affect the age at which the stages (which are qualitatively different from each other) are attained, but the sequence should be universal. Generally, there is stronger support for the universality of the less advanced stage (sensorimotor) than the more advanced stage (formal operations) (Dasen, 1977). This linear Piagetian approach to cultural variations precludes dynamic and nonlinear view of cognitive development.

Today, the question is reframed within a different and exciting research program on geometry and number (in line with the general 'Kantian research program' in the *Cognitive Sciences*: Dehaene and Brannon, 2010; Izard et al., 2011). In a famous paper, Dehaene and colleagues explored whether geometry constitutes a core set of intuitions present in all humans, regardless of their language or schooling (Dehaene et al., 2006). They used two nonverbal tasks to probe the conceptual underpinnings of geometry in the Mundurukú, an isolated Amazonian indigenous group (already studied by Pica et al., 2004; for arithmetical abilities). Mundurukú children and adults spontaneously used basic geometric concepts such as points, lines, parallelism, or right angles to detect intruders in simple pictures, and they used distance, angle, and sense relationships in geometrical maps to locate hidden objects. Dehaene's results provided evidence for geometrical intuitions in the absence of schooling, experience with graphic symbols or maps, or a rich language of geometrical terms.

In a subsequent study, the same authors showed distinct intuitions of the number scale in Western and Amazonian indigenous cultures (Dehaene et al., 2008). This study was rooted in previous developmental experiments that showed a remarkable shift in the child's conception of how numbers map onto space, from logarithmic to linear mappings, between the first and fourth grades, depending on experience and the range of numbers tested (Booth and Siegler, 2006; Siegler and Booth, 2004; Siegler and Opfer, 2003). However, a logarithmic strategy may remain dormant in all of us for very large numbers or whenever we approximate numbers (Banks and Coleman, 1981), including prices (Dehaene and Marques, 2002). Consequently, the log and linear scales may be deeply embedded in all of our mental activities. Moreover, the mapping of numbers onto space through the logarithmic strategy plays an essential role in mathematical sciences. In their cross-cultural study, Dehaene et al. (2008) tested whether this mapping is a cultural invention or a universal intuition shared by all humans, regardless of culture and education. They probed number-space mappings in the Mundurukú, the same Amazonian indigenous culture as in the previous study (a group with a reduced numerical lexicon and little or no formal education). At all ages, the Mundurukú mapped symbolic and nonsymbolic numbers onto a logarithmic scale, whereas the Western adults used linear mapping with small or symbolic numbers and logarithmic mapping when the numbers were presented nonsymbolically under conditions that discouraged counting. According to Dehaene, this demonstration indicated that the mapping of numbers onto space is a universal intuition and that this initial intuition of number is logarithmic. The concept of a linear number line appeared to be a cultural invention that failed to develop in the absence of formal education.

These new data on cultural variations illustrate, through a dynamical system of cognitive growth, how cultural experiences may alter the weight of strategies used by children or adults (see Geary, 1996; Lubin et al., 2006; Saxe, 1999; for previous cross-cultural or cross-linguistic studies on mathematical abilities; see also Dasen and Mishra, 2013; for cross-cultural studies on the development of geocentric spatial language). Future studies can explore systematically how cultural variations may modulate the competition between cognitive strategies in the brain, with the idea that heuristics (sometimes, algorithms) are culture-dependent strategies. From this point of view, educational policy should focus on interventions that can aid executive function, particularly inhibitory control, in children (Diamond et al., 2007; Diamond and Lee, 2011; Houdé, 2007). Prefrontal executive control is probably a general culture-independent potential shared by all humans in their genetic heritage (Thompson et al., 2001), even if its ontogenetic maturation is late (Casey et al., 2005), although the respective weights of cognitive strategies to inhibit or activate, case by case, might depend on context and culture.

Abstract

Since very early days, the phenomenon of learning by individuals has fascinated both psychologists and philosophers alike. The complexity of the human learning phenomenon gave rise to different theories or schools of thoughts. One of the most influential schools of thought in educational psychology is cognitivism.

Cognitive theories explain how behavior changes as a result of people's perception, transformation, processing, storage, and retrieval of information in contrast to behaviorist theories that put emphasis only on observable behavior of individuals. Although the origin of cognitive development theories can be traced back to the early twentieth century, it became known to psychologists and academicians through the work of the Swiss psychologist Jean Piaget and the Russian psychologist Lev Vygotsky. Cognitive development theories provide a rich and descriptive data to enhance learning among pupils and to promote their healthy cognitive and emotional developmental needs.

Introduction

The phenomenon of human learning has fascinated humans of all ages. Psychologists have tried to understand and explain how human beings acquire and accumulate information and how their thinking ability develops over a period of time. Psychology as a discipline of human inquiry was mainly concerned with the study of functioning of the mind, including learning. Thus, many psychologists, particularly during the nineteenth and twentieth centuries tried to explain the process of human learning and to discover the laws governing this important human phenomenon. It was believed that proper understanding of the phenomenon will lead to guiding teachers to implement effective teaching and thus improving the teaching–learning process. Many psychologists contributed toward development of the discipline and proposed different theories. For the sake of clear understanding, different authors have grouped these theories into three categories or schools of thoughts. One important school of thought and the most dominant in recent years is cognitivism, the school of thought that tries to explain the origin of intellect in human beings (Piaget, 1952) and how their ability to learn and acquire new information evolves from birth to maturity.

Emergence of Cognitivism

Cognitivism as a school of thought emerged in response to behaviorism in mid-1970s (Bell-Gredler, 1986). Two factors contributed toward the development of cognitive psychology. First, the behaviorist theories could not offer plausible explanation of higher order mental processes like thinking and processing of information. Thus psychologists became frustrated with the limitation of behaviorist psychology to explain internal mental processes of perception, insight, and meaning (Iqbal, 1997). The second factor was the availability of computers and research in areas like linguistics (Baars, 1986; Weisberg and Reeves, 2013) that provided the model for explaining human information processing. In cognitive psychology, the emphasis is on the observable behavior of the individuals, but it is equally important to consider whatever goes inside the mind of that individual (Flavell et al., 1993). However, there are different views to explain that mechanism. Cognitive psychologists believed that human learning is a complex phenomenon and hence cannot be understood by breaking it down into simpler parts.

Early Development

The founder of this school of thought is said to be a German psychologist Max Wertheimer (1880–1943). This school of thought is known as classical Gestalt psychology. Gestalt means configuration. According to this view, learning is the change in figure–ground relationship or the development of a better Gestalt. In Gestalt psychology, the learner sees a total picture with all its parts interrelated (Reilly and Lewis, 1991). The way in which a learner sees any part of the picture depends on its relationship with other parts. Seeing only part/s of a picture will not be meaningful (Pillsbury, 1933). According to this view, learning cannot be reduced to simple observable behavior only.

The second psychologist who contributed toward the development of Gestalt psychology was Wolfgang Kohler (1887–1967). He studied problem solving in apes by putting them in a cage with a bunch of bananas hanged in the cage from the ceiling. The apes could not reach the bananas. There were two boxes in the cage. The apes stacked these boxes together, climbed on top of the boxes, and reached the bananas. Kohler did not see any evidence of trial and error or gradual conditioning process or any stimulus-response (S-R) association as envisioned by behaviorists. On the other hand, the ape perceived a problem situation and tried to solve it. This finding of solution resembled a burst of insight or understanding, following a moment of little pondering, in turn followed by a sudden correct behavior. In the beginning, the ape could not understand the relationship between ceiling, boxes, and bananas. But, when it was put in a problem situation, it had a new perception of all these parts and restructured the situation in the mind and arrived at a solution. It is this new perception, 'this better gestalt,' that allowed the apes to stack the boxes and reach the bananas. The important point of this perception is how different elements are seen relative to the total picture.

The third contributor to the development of cognitive model of learning was Kurt Lewin (1890–1947). Lewin (1936)

theorized that behavior is the result of the situation as perceived by individuals, as individuals relate it to their own needs and purpose. According to Lewin, individuals' perception of a situation is called their 'cognitive field' and the world as they sees or experiences it, including goals as well as barriers to them, is called their 'life space.' Lewin elaborates that an individual faces conflicts in reaching his or her goals. For example, an individual seeks to reach a particular goal that he or she sees in his or her life space. But, the individual finds that there are certain barriers in the achievement of that desired goal. These are the forces that push the individual in an opposite direction. If positive valences are strong enough, the individual will overcome the barrier and reach the goal. However, if the negative valances are strong enough, the individual will find some reason to abandon the task. According to the field theory, the important element is the situation as perceived by the individual. This is the key element in changing behavior. An individual's behavior can be understood and predicted if how the individual perceives the situation and what he or she expects out of it can be found. Similarly, if an individual is able to change his or her perception, he or she will be able to change his or her behavior as well.

The *Gestalt psychology* could not get due attention of educated circles. Instead, behaviorism became a dominant tradition, particularly in American institutions. However, toward the second half of the twentieth century, the school of thought alternative to behaviorism reemerged as cognitivism because of the work of Jean Piaget, Lev Vygotsky, and later of Jerome Bruner. This article briefly describes cognitive theory of Jean Piaget and Lev Vygotsky and its implication for education and teaching. For detailed description of these theories and that of Jerome Burner, the readers are referred to other articles, particularly Piaget's Theory of Cognitive Development (*see* Piaget's Theory of Cognitive Development), Vygotsky's Theory of Cognitive Development (*see* Vygotsky's Theory of Cognitive Development), and Jerome Bruner's Theory of Cognitive Development (*see* Bruner's Theory of Cognitive Development).

Jean Piaget's Theory of Cognitive Development

The intellectual development theory that has had a great bearing on the practice of education during the second half of twentieth century is that of the Swiss psychologist Jean Piaget. His contribution to the development of cognitive tradition is unparalleled. His propositions have generated a lot of interest and research in the field. His theory of cognitive development is most encompassing and comprehensive than any of his predecessors. Though he was researching and writing on this issue of human importance since the beginning of the twentieth century, his findings got recognition nearly 50 years later. Much of the current understanding of children's thinking comes from Piaget's notions.

The basic premise of Piaget's theory is that the complex form of human behavior cannot be reduced to a simple form. He was of the view that complex problem-solving behavior cannot be reduced to a set of conditioned operant, as Skinner would have us believe. Neither can such complex behaviors be reduced to classically conditioned responses, as Pavlov envisioned. Complex phenomena have to be studied in their entirety and with all of their complexity, and there are laws of complex forms of behavior as there are laws of simple forms of behavior, but these are different laws (Iqbal, 1997). Piaget does not deny the existence of either operant or classical conditioning as phenomena, but he views them as referring to trivial aspects of human behavior. Thus, he understands that behavior is influenced by what operant psychologists call reinforcements and others call incentives, but he does not see these as having any relevance to human intellectual performance.

According to Piaget, human beings are not passive recipients of stimuli from the outside world; rather they have to play an active role in their learning. In order to learn, the learner needs to process the information that he receives through senses in the form of stimuli. Active interaction of the child with his or her environment is the salient feature of Piaget's theory. This interaction plays an important role in determining the child's progress from one stage to the other. He did not conceptualize behavior and reinforcement as behaviorists do (Wadsworth, 1989). Being a developmental psychologist, he was more interested in the internal processes of brain and in studying the changes in the cognitive functioning of individuals with the passage of time (Piaget, 1970). He was of the view that thought processes in children are quite different from those in adults as they are not 'little adults.' They have their own unique way of thinking and interpreting the world, which may be different from adults' view but is true with respect to the age group they belong. The term cognition means the product as well as the process of knowing. From birth to maturation, an individual changes the perception of world around him or her. With the passage of time the individual also changes the strategies of knowing the world. This process is called cognitive development (Inhelder and Piaget, 1958).

Piaget contends that the cognitive development of an individual is the outcome an interaction between three factors: heredity, maturation, and the environment in which the child operates. Heredity is the genetic potential of an individual that is received from parents. Maturation is the unfolding of that genetic potential with the passage of time. The environment, both physical and intellectual, provides the necessary stimuli, inputs, and experiences for cognitive stimulation through which the individual constructs his or her knowledge (see **Figure 1**).

According to Piaget cognitive development has two important aspects: the process or mechanism of cognitive development and the outcome of that developmental process (Weisberg and Reeves, 2013).

The Mechanism of Cognitive Development

Before discussing Piaget's stages of development, it is very important to take a note of his main concepts. Piaget used the constructs of schemata, assimilation, accommodation, and equilibration to describe the process of cognitive development and consequently learning (Wadsworth, 1989).

'Schemes' are patterns of behavior that children show in dealing with objects in space. In case of children, schemes can be simple like the pattern of behavior shown by a child in grasping an object within his or her reach. It is complex in case of adults. They show it when they try to solve a complex mathematical problem.

Figure 1 Factors affecting cognitive development.

Assimilation is an internal organizational process used by individuals to make sense of the world around them. Through the process of assimilation, new incoming information becomes part of the old one. However, it is very important for the new knowledge to have best similarity with the old or existing structure/scheme (Gallagher and Reid, 2002; Fischer and Hencke, 1996). In contrast, 'accommodation' occurs when one tries to modify the old schemas to fit the new information in his or her cognitive structures. Piaget says that when the organism fails to handle the new situation with the help of the previously learned pattern of behavior, some sort of inequilibrium or imbalance is created. However, the individual tries to reduce such imbalance. The individual does so by focusing attention on the stimuli that has caused the imbalance. The individual develops new schemes or adopts old ones until the equilibrium is restored. This process of restoring balance is called equilibration (Gallagher and Reid, 2002). Thus the individual uses either assimilation or accommodation to make new information part of his or her schemes and hence learning occurs (Fischer and Hencke, 1996).

Piaget argues that these processes are invariant and continue throughout the life span of an individual. However, as a result of these processes of assimilation and accommodation, the cognitive system itself changes and cognitive development occurs (Piaget, 1972). The mechanism of cognitive development is illustrated in **Figure 2**.

Stages of Cognitive Development

According to Piaget, a child is in a constant state of cognitive change throughout her entire span of life, particularly from her date of birth to the period of adolescence. During this period, an individual passes through different and clearly noticeable stages of cognition. Piaget divides this developmental period into four stages. Each stage is reached or attained by an individual at a particular age. In other words, cognitive development of every individual is age and stage bound. All children invariably go through these stages of cognition in a fixed order. Piaget called these four stages as sensory motor, preoperational, concrete operational, and formal operational. Development of a new stage incorporates the former stage. These stages and the ages at which the individual attains these are given in **Table 1**.

These periods of attainment of different stages are just suggestive. Piaget (1972) himself was of the view that the age at which an individual child attains a particular stage is not fixed.

Figure 2 Mechanism of cognitive development.

Table 1 Stages of cognitive and their characteristics

Stage/age	*Characteristics*
1. Sensorimotor (0–2 years)	1. Begins to make use of imitation, memory, and thought 2. Begins to recognize that objects do not seem to exist when they are hidden 3. Moves from reflex action to goal-directed activity
2. Preoperational (2–7 years)	1. Gradually develops use of language and ability to think in symbolic form 2. Able to think logically in one direction 3. Has difficulties seeing another person's point of view
3. Concrete operational (7–11 years)	1. Able to solve concrete (hands-on) problems in a logical fashion 2. Understand conservation and is able to classify and seriate 3. Understand reversibility
4. Formal operational (11–adult)	1. Able to solve abstract problems in a logical fashion 2. Becomes more scientific in thinking 3. Develops concerns about social issues and identity

He seems to accept the idea that the age at which the stages occur can vary from individual to individual depending on the nature of both an individual's experiences and his or her hereditary potential. What is more important is the idea that children can demonstrate specific thinking abilities at the specific age. They can perform a set of mental functions at one stage and not at the other. A higher stage of mental function is built upon and incorporates the lower stage or stages and not the other way round. Piaget calls these mental functions as operations. Thus, a child at the preoperational stage is able to demonstrate operations specific to that age and is not able to perform operations of concrete operational stage.

Vygotsky's Theory of Cognitive Development

Piaget's is not the only theory of children's cognitive development. Another theory that has received increased attention in recent years was proposed by Lev Vygotsky. Like Piaget, the Russian psychologist Lev Vygotsky (1896–1934) also believed that children actively construct their knowledge, but he put more emphasis on social interaction. Both Piaget's and Vygotsky's ideas went unnoticed by the academic community for many years. These were introduced to American audiences through English translations in the 1960s. Since then the psychologists and educators, not only in America but also in other parts of the world, have shown an increased interest in Vygotsky's views and its implications for education (Newman and Holzman, 1993).

Vygotsky's views about cognitive development can be summarized in three points (Daniels, 2008).

1. The child's cognitive skills can be understood only when they are developmentally analyzed and interpreted. For him, it is very important to measure how children form concepts and transform them from one stage to another, and such processes must be observed throughout their development gradually and subsequently (Daniels, 2008).
2. Cognitive skills are mediated through psychological tools or mediators that facilitate in transforming and assessing mental processes and functions such as language, words, counting systems, mnemonic techniques, algebraic symbols, artwork, writing patterns, maps, diagrams, drawings, and other sorts of signs and discourse. Such tools nature is social and artificial rather than organic. He proposed that language is the most important tool in this regard and for children it serves as a tool to plan activities and solve problems in daily life (Daniels, 2008).
3. Vygotsky claimed that cognitive skills have their origins in social relations and are embedded in a sociocultural backdrop (Daniels, 2005). He emphasized that a child's development cannot be studied in isolation from social and cultural activities. Language, for example, is a very important social tool that plays a very important role in development. Similarly, various cultures use different techniques as memory strategies and developing mathematical concepts (Reid et al., 1982).

Vygotsky coined different terminologies to propose the concepts that explain the relationship between society, learning, and development of an individual, which reflect his conceptualization about social origin of cognitive functioning. Three key concepts capture the essence of what Vygotsky means by social origin of cognitive functioning. These are (1) zone of proximal development, (2) scaffolding, and (3) the role of language as a tool for promoting cognitive development (Vygotsky, 1978).

Zone of Proximal Development

- Zone of proximal development, now called the zone of potential development (ZPD) is a term that Vygotsky used to explain the range of development. He is of the view that every individual has two levels of development: a lower level that each is able to attain under normal circumstances and an upper level that each can attain under the influence of an adult or capable peer. The difference between these two levels is the ZPD (Daniels, 2005). Vygotsky's articulation of the ZPD underscores his belief in the importance of social influences, especially instruction, on children's cognitive development.

Scaffolding

- Scaffolding is a concept closely linked with the zone of proximal development. It explains the nature and kind of help and guidance afforded to the child by an adult in solving a relatively difficult task. Vygotsky emphasizes that instead of providing a direct solution to the problem, an adult or more knowledgeable person should adjust the level of guidance to help the learner to arrive at the solution. Direct instruction may be provided when the task is new or more difficult.

  Dialog, discussion, questions, prompts, and clues are different tools that are used during scaffolding. By using

these techniques, the teacher or peer provides logical direction to the thought processes of the more novice learner.

- Language and thought

  Vygotsky (1978) puts an added emphasis on the use of language by children from an early age. He believes that children's use of language is intimately linked with the development of their thought. He believed that young children use language not only to communicate with adults in their surroundings or care givers, but regulate their thinking and behavior as well. Thus, for Vygotsky, children's inner or private speech is an important tool for development of thoughts.

  Vygotsky believed that children's use of language has two dimensions, external and internal. External dimension refers to their use of language to communicate with others and internal dimension refers to their inward focus on their own thoughts.

Vygotsky's views about language are in direct contrast with those of Piaget. Piaget views children's language as nonsocial or egocentric speech and their self-talk being immature thought. In contrast, Vygotsky believed that the language is socially based and governs and guides the children from very early stage (Scholnick et al., 1999). It is equally evident that both Vygotsky and Piaget have given due attention to social relationships and cultural aspects in the process of learning and knowledge enhancement (Smith et al., 1997).

Role of Culture in Cognitive Development

Cognitive development theorists, particularly Vygotsky, have put an added emphasis on the role that a particular culture plays in the cognitive development of individuals. Although Piaget recognizes the role of interaction of children with the environment in unfolding their innate abilities, he puts an upper limit on such development, which is determined by the phenomenon called maturation. Piaget believes the young child to be interacting with the environment on its own and developing the concepts of conservation, seriation, and object permanence without the help of others solely on the basis of his or her observation. This age-bound developmental nature of cognition necessitates that a teacher should teach an age-appropriate and developmentally appropriate content and should adopt instructional strategies accordingly. Vygotsky, on the other hand, believes that culture in the form of social interaction plays a major role in the cognitive development of individuals from very early age. He views cognitive development as a social and cultural process. As a matter of fact, it is this idea that distinguishes Vygotsky from Piaget. Vygotsky's quoted statement reads:

> … every function in the child's … development appears twice: first, on the social level, and later, on the individual level; first between people (interpsychological), and then inside the child (intrapsychological) …
>
> Vygotsky, 1978: p. 57

It was this cultural aspect of human's cognitive development that inspired Vygotsky to propose the concept of zone of proximal (potential) development. Vygotsky defines the ZPD in the following words.

> … the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers.
>
